The Cortex: The outstanding feature of the cortex was the prominence of the small blood vessels Practically every capillary stood out as the result of the swelling of their lining cells New blood vessel formation was the rule throughout the entire cortex. Vessels that were slightly larger showed a thickening and hyalinization of the walls, which eaused them also to stand out in marked relief. Around some of the blood vessels in the eortex, but particularly in the subcortex, one met very frequently with adventitial collections of phagocytic cells that were over-filled with a dark green pigment (Fig. 3). These pigment granules were for the most part engulfed in phagocytic elements but occasionally were free in the adventitial space. Usually around the vessels of this sort there was a very definite space of His, in which one could at times see a very grannlar material, evidence of the edema that was pres-In the subcortex in this case, the blood vessels showed to a greater degree the swelling that was also found in the cortex.

The ganglion cells within the cortex showed much less degenerative changes than in Case I. As a rule the cortical architectural picture was well maintained even though glia was increased Many ganglion cells showed a pallor; very many showed a tendency towards ischemic change, and very many were comparatively normal. Here also one got the distinct impression that the change in the ganglion cells occurred in foci, and, while there were no actual areas of

ischemia with complete loss of ganglion cells, still numerous foci were present where the ganglion cells were much more involved than in neighbor-

ing areas.

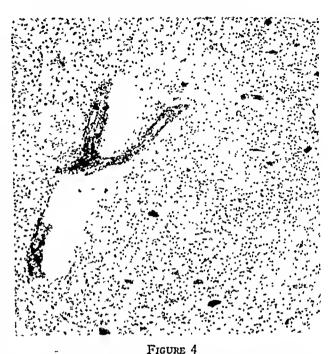

There was a very evident increase of glia that could be visualized even with the cell stain, and here again the involvement was more marked in certain focal areas than in others. There was no uniform rule as to the areas involved. It might be stated, as a general principle, that the third cortical layer appeared to suffer most damage, but this also was a variable condition. One occasionally saw Gëfasspaketten.

Case 2. Cortico-subcortical area showing perivascular collections of pigment-laden phagocytic cells. Intense general gliosis evident. (Toluidine blue stain.)

The Cerebellum: The meninges over the cerebellum showed the same general characteristics as over the cerebrum. There was a much more marked involvement of the cerebellar tissue than in any other part of the intracranial structures. There was a uniform pallor of the Purkinje cells. but no actual destruction. The molecular layer showed a great increase of the small blood vessels, all of which stood out rather prominently as the result of the swelling of their lining cells. The outstanding feature of the cerebellum was the change in the dentate nucleus (Fig. 4). Not only were there severe degenerative manifestations in the cells of the dentatum, but there was a considerable destruction in and around this nucleus, which resembled to a remarkable degree a patch of multiple sclerosis. The tissue was completely overrun by small glial nuclei. New vessel formation was a feature. Perivascular collections of round cells were present in and around these patches. In some of the adventitial spaces the number of round cells was so great

that at first glance it resembled an acute inflammatory process, but on careful study one found in the adventitial spaces a great deal of yellowish and greenish pigment as evidence of the destructive process that was going on.

Case 2. Dentate nucleus of cerebellum—Toluidine blue stain. Ganglion cell destruction, gliosis, and perivascular collaring of vessel seen.

Case 3. 23-52. Summary: A male, aged 55, a lead worker for six years, frequently was obliged to stop work because of colicky pains in the abdomen, general weakness, pallor and constipation. The condition gradually grew worse, and in this state he developed pneumonia, after exposure, and died. The blood picture showed marked secondary anemia, stippling of red cells, and the pathology at autopsy revealed lobar pneumonia, and cloudy swelling of the body organs.

J. W. S., a white male, aged 55, was admitted to the Philadelphia General Hospital, February 24, 1923, service of Dr. S. S. Cohen, and died February 27, 1923. The admission complaint was general weakness. He had worked in a factory wherein lead was used considerably, for a period of six years, and it is reported that he was obliged frequently to lay off for varying periods of time, because of general weakness, abdominal pains, pallor, and constipation. The past history stated that he had had typhoid fever at nine years of age, and influenza in 1918. Three weeks before admission to the hospital, he was exposed to cold and wet, following which he developed a cough and pneumonia, for which he was admitted to the hospital.

Examination on Admission: He was quite emaciated. There was a distinct blue line along the gums. The pupils were small, but reacted

slightly to light and in accommodation. The vessels were thickened, there was general abdominal tenderices and evidences of lobar pneumonia. The tendon reflexes were present and equal, but diminished.

Labaratary Examination The urine was smoky, and was chemically negative for lead The hemoglobin was 60%, red cell count 2,154,000, white count 13,000, of which 82% were polynuclear cells There was marked stippling of the red cells Blood Wassermann was negative

Caurse He grew rapidly worse and died within three days after admission to the hospital

Pathalagy Examination revealed terminal pneumonia chronic myocarditis, chronic interstitial nephritis, splenitis, and cloudy swelling of the liver

Grass evamination of the brain showed a moderate enlargement, with pallor of the entire brain substance. The pia-arachinoid was slightly thickened and opaque. The basal vessels were thin and fibrous, and contained no plaques

Microscopic Examination The meninges were definitely fibrous and mildly edematous and contained within their meshes large phagocytic elements in groups of considerable numbers

The Cartex showed no disturbance of its general architecture, but there were noticeable areas of varying sizes in which the ganglion cells showed degenerations of all kinds, mainly however, tending to liquefaction

The outstanding feature of the cortex was the prominence of the small blood vessels. While not an absolutely uniform process, nearly the entire cortex showed that the cells lining the small capillaries were unusually prominent as the result of swelling, and new vessel formation was a feature

Glia was moderately increased Fat stains showed a mild increase particularly in the gan-

The cerebellum showed a mild degeneration in the Purkinje cells, as well as an increase in Bergmann's gha layer. The vessels in the mole cular layer showed the same endarteritic changes as were present in the cerebral cortex.

Case 4 31 158 Summary A white male, aged 70, a painter most of his life, was taken ill with colicky pains in the abdomen, and later emaciation, secondary anemia, weakness and dyspnea developed. He presented a blue line along the gums, and a retracted abdomen. There was marked muscle weakness, stippling of the red blood cells, marked secondary anemia, no response to treatment, and death

C S, a white male, aged 70, was admitted to the Philadelphia General Hospital, service of Dr J W McConnell, June 6, 1931, and died June 8, 1931 The Instory given stated he had been a painter most of his adult life For three years he had felt weak and had lost weight He had colle like pains in abdomen for one year He

stopped work six days before admission, because of a fall

Liaminatian on admissian revealed a very emaciated man, having marked dyspuca answers were almost maudible gasps, but always iclevant He was very weak. There were no abnormalities of the scalp or skull showed a gray pallor, the pupils were equal, round, and reacted to light and in accommoda tions, the extra ocular movements were slow, but full, the teeth were few and carious, and a blue line was seen on the gums, the tongue was brown and coated The lungs revealed rales at both bases and respirations were rapid and feeble heart was rapid, but there were no murmurs blood pressure was 108/54 Radial vessels were The abdomen was relaxed was no rigidity of ncck and no tenderness general he was dehydrated

Neurolagical evanination the second day revealed him to be semi-conscious. All the cranial nerves were apparently normal. There were no palsies, but he was very weak. There was general wasting of all muscles, but this was nutritional rather than atrophy. There was bilateral wrist drop. There was no tremor of the muscles and no sensory disturbance, and all the tendon reflexes were active and equal. There was no clonus and no Babinski.

Laboratory Examinations Urine showed a specific gravity of 1012, a heavy trace of albumin and a few epithelial cells. The hemoglobin was 70%, red cell count 4,260,000, white count 11,000, of which 85% were polynuclear cells. There were many red cells showing stippling Blood Wassermann was negative.

Caurse Two days after admission he became suddenly weak and died that day The temperature during these few days in the hospital ranged from 97 in the morning to 99 in the evening, pulse from 60 to 90, respirations from 25 to 46

Patholagy Post mortem revealed general arteriosclerosis, myocardial degeneration, brown atrophy of the heart muscle, congestion of all bodily organs, plus pigmentary infiltration of bowels, kidneys and liver

Microscapic Examination Meninges The meninges showed a variable picture For the most part there was a very marked fibrosis and edema with occasional groups of cells of the phagocytic type, but without inflainmatory elements

The Blaad Vessels The large vessels were remarkably well preserved, especially for a patient who had been working with lead practically all his adult hie There was little or no atheroma The muscle was, however, fibrotic and took a metachromatic tint

The Small Vessels Throughout the entire cortex the outstanding feature was the prominence of the smallest blood vessels For the most part the lining cells were swollen and at times

projected into the lumen. New blood vessel for-

mation was a universal finding.

The Cortex itself showed a most profound change. One could see, first of all, the prominence of the small blood vessels and new blood vessel formation. There was also an edema of the tissue to such a degree that the perivascular spaces were greatly distended. The ganglion cells showed definite degeneration, but the involvement was not a uniform one. Entire areas of the cortex showed normal ganglion cell pictures. Here and there were noted comparatively sharply circumscribed areas in which the ganglion cells were reduced to shadows. In places these areas had become confluent, so that they formed relatively large patches. The glia was markedly increased and this was more marked in areas of ganglion cell loss. The glia was mainly of the The Hortega stains for the astrocytic type. the microglia showed practically no increase.

The Subcortex likewise showed profound changes. Not only was there a definite widening of the perivascular spaces of His, but most of them showed the presence of granular debris as well as greenish pigment granules, some of which were still contained within phagocytic elements. The small blood vessels showed even more intensely than the cortex the swelling of their lining cells. There was a very definite macroglial proliferation in the subcortex at the expense of the oligodendroglia. One could not make out a focal distribution for these changes as was present in the cortex, because the subcortex appeared to be fairly uniformly involved.

COMMENT

We have herein described four cases of lead intoxication in which definite changes in the brain have been shown. These changes can be discussed under two headings: (1) Changes in the blood vessels, and (2) Changes in the ganglion cells.

vessels, and (2) Changes in the ganglion cells.
(1) Changes in the Blood Vessels: It has been our finding, and the findings of all who have investigated this subject, (Hassin (8), Bonfiglio (9),) experimentally or otherwise, that the vascular changes must be considered from two standpoints: (a) the large blood vessels and (b) the small blood vessels. It is recognized that lead hastens arteriosclerotic changes, but there is no specific or characteristic change in the larger vessels due to this poison. In the small vessels we have excellent demonstrations of the effect of lead in our cases. In all, the small vessels appeared to bear the brunt of the attack. The cells lining the small vessels were noticeably more prominent, they were swollen and pyknotic, and lateral budding resulting in new vessel formation took place.

(2) Changes in the Ganglion Cells: It is possible, on the same basis, to account for the changes in the ganglion cells, and also for the secondary glia change which is prominent and mentioned by all who have had occasion to dis-

cuss this subject. (Tuthill (10), Staemmuer (1), Mott (11), Ferraro and Hernandez (12).) Ischemic ganglion cell change should be the characteristic finding in this condition, but this is not always the case. We find simple chromatolysis (cloudy swelling) that is similar in all respects to the change in the body organs. Ischemia, however, is present and even completely acellular areas (verödungsherde). These were evidences of focal anoxemia. Lipoid accumulation, while not a prominent feature, was present and has been described. It is possible to account for most of these changes on the basis of a direct toxic action, but it is singular that the cerebral cortex is more susceptible than is the brain stem. This susceptibility of the cortex occurs also in syphilis, where the small vessels of the cortex are practically alone attacked.

From results of the cerebral studies one is impressed by the fact that, just as in any toxic or infectious process (Winkelman & Eckel (13)), the brunt of the attack is primarily on the small vessels, with minor direct action on the ganglion cells.

From the results of our microscopic studies on the brains of four patients who showed severe cerebral symptoms as the result of lead poisoning, we were impressed by the fact that, while the cortex at first glance appeared to be uniformly involved, yet on careful analysis we could very easily determine that the cortex was involved in an irregular manner. For the most part one could note a moth-eaten appearance to the cortex as the result of a variable number of foci of degeneration. These, at times, were so numerous that they became confluent, and it was then that the cortex appeared uniformly involved. It was only in the older areas, or in cases that were not so extensively involved, that the focal nature of the condition was recognized. Throughout most of the cortex one could see areas of practically normal ganglion cells in the midst of foci of very severe destruction. It has been recognized for a long time that the acute swelling and the other degeneration of the ganglion cells that result from a generalized toxic process occur throughout the entire cortex (Hassin, Winkelman & Eckel). All who have written on the subject of acute swelling of the ganglion cells have stressed this particular In our cases, the ganglion cells were not uniformly or universally involved, and as can be seen from the several photomicrographs which have been presented, the involvement in lead poisoning, as far as the cortex is concerned, is not a uniform condition. This factor is stressed because it, alone, helps to explain the mechanism of the process. We know that in endarteritis of the small vessels not every vessel or area is involved by the process, but that it tends to be patchy and involves some areas more than others. This is exactly the condition that we see in endarteritis syphilitica, in endarteritis due to any other

toxin, and the same condition prevails with regard to lead poisoning. That this is plausible can be gleaned from the fact that lead does have an affinity for blood vessels, and produces earlier arteriosclerotic changes than would ordinarily occur in the patient. This same affinity for the blood vessels can be very easily noted in the vessels of the brain and we feel that we are able to explain the mechanism of the action of lead no this general basis.

The importance of the mechanism of action of lead on the brain will, of course, point the way to the method of therapeusis. An effort must be made, if the brain is to be protected against the ravages of poisoning by lead, to so after the chemical composition of the blood, that the lead does not have the opportunity of acting on the

blood vessel walls.

first as after the colic that results from lead intoxication, so also the cerebral manifestations may be relieved for a while, and they may completely disappear if the ingestion of lead is stopped. The question may come up as how the patient is able to make a recovery if the changes in the brain are such as we have described. This is very easily explained when it is realized that even in severe arteriosclerosis, where numerous small areas of softening are present throughout the entire brain substance, the patient may show no focal symptoms that can be diagnosed clinically. So it is with cases of lead poisoning. It would not mean that the patient has not suffered damage to the brain, but it is to be explained by the fact that the damage to the brain is not sufficient to produce gross clinical manifestations. When, however, the changes in the brain arc so marked and the focal areas so numerous, then there is no compensation on the part of the brain tissue, and the patient exhibits clinical manifestations as the result of damage to many areas of the cortex.

The question of the convulsions, which has already been discussed briefly, merits further discussion in view of our findings. It is true that we have found the same changes here, in our case of lead poisoning, as in cases of a severe convulsive state. It is impossible to tell whether or not changes in the brain, which are found in convulsive states, are primary or secondary, and for that reason the explanation of the mechanism of the convulsions which occur in lead poisoning will aid materially in furthering the solution of the problem of the convulsive states. In none of our cases was there an involvement of Sommer's sector, as occurs frequently in the convulsive state (Spielmeyer (4)), but Sommer's sector is not involved in every case of convulsions. Its vulnerability probably accounts for its involvement in so many different conditions. We have had occasions to see this area involved in arteriosclerosis, even in the absence of convulsions. and the reverse also holds true.

One must realize that the swelling of the lining cells, which occurs in lead poisoning, can occur quickly and disappear quickly, under appropriate conditions. The mere reduction in the amount of oxygen to a part of the brain will be effective in producing this change, and this can occur in the course of minutes. The mere giving of oxygen to that part can cause the swelling to disappear almost as quickly as it had appeared.

We have thus to deal, in lead poisoning, as far as the brain is concerned, with a fairly generalized, although not uniformly so, involvement of the small blood vessels. There is, as in any other toxic and infectious condition, a prominence of the small blood vessels, which is, at times, out of proportion to the rest of the cerebral picture. There is also a definite new formation of blood vessels, so that even in the ordinary toluidine blue preparations the number of small blood vessels in each field is increased to an enormous degree. Eventually, as the case progresses, there is found besides this new formation of capillaries, an increase in the tortuosity of the medium sized blood vessels, so that there results a picture that is known as Gefässpaketten, where we see three or even more lumina of blood vessels, which are seen in the chronic stages of all infectious and toxic processes. It is believed that there necurs an accumulation of fluid between the muscle bundles in the media with the consequent coagulation, and at times, actual destruction of the muscle fibers. This great change in blood vessels, while easily visible in the ordinary cell preparations, are brought out vividly in the silver fibril stain of Klarfeld, and are even visible in the Cajal preparations.

The spotty character of the change is brought home to us again by the occurrence of minute areas of degeneration in various stages up to the formation of completely acellular foci and lessening in intensity to mild degenerative changes in ganglion cells in one focal area. It is a rather striking thing, as shown in the photographs, that the ganglion cells, within one small focus, might show severe changes with small shadow cell formation, while the ganglinn cells immediately surrounding this area are practically within normal . That this is not the usual picture of a process wherein the ganglion cells are involved primarily, needs only to be mentioned to be appreciated. In acute swelling of the ganglion cells, which occurs as the result of a generalized direct involvement of the ganglion cells themselves, the process is universal and everyone who has studied this condition has stressed this one particular factor. In lead poisoning this has not been our finding in any of the cases, but rather a disturbance of the ganglion cells in foci.

It must be stressed also, that there is no uniform involvement of the brain substance as far as these areas are concerned. At times one finds field after field of the cortex perfectly normal,

and then two or three areas where abnormalities occur. This is to be stressed because if one depends on one small section for his idea of the cortical change, he will be led to believe that the cortex has suffered no damage. That this is not true can be seen from a study of numerous areas of the cortex.

Occasionally one sees, within the brain substance, blood vessels which contain numerous phagocytic cells within the perivascular spaces. Many times pigment within the gitter cells, brownish black in color, such as one sees not infrequently in the neighborhood of hemorrhage, is observed. In no cases were hemorrhages found in the brain. An effort was made, therefore, to determine the nature of this pigment. Special stains for lead were devised, but no result could be postulated because the same type of reaction could be obtained in the neighborhood of hemorrhages. It is, therefore, going to be necessary to examine chemically, fresh brain material for its lead content, rather than to depend on the stain-This was not done because no ing reaction. fresh material was available at this time.

It must be stressed that the cortex itself was not the only part of the central nervous system that was involved. The photomicrograph from

the dentate nucleus (Fig. 4), shows a rather intense degeneration of the dentatum (from Case 2). Here we see a rather diffuse involvement f the dentate, with a marked gliosis and a collection of cells in the neighboring vessel, which at first glance, bears a striking resemblance to the round cell infiltration of the lymphocytic type. That these cells are not lymphocytes can be easily determined by fat stains, which show many of the lipoid granules.

SUMMARY AND CONCLUSIONS

- 1. Lead poisoning affects the brain and produces a clinical picture known under the term of encephalopathy.
- 2. While ganglion cell degeneration occurs and has been described, it is our finding that this is not a uniform process, but occurs secondarily as result of changes in the small vessels which produces greater or less anoxemia of small focal
- Our conception of the action of lead on the brain is that it occurs through blood vessel changes.
- 4. The glial changes in lead poisoning are secondary to the vascular disturbance.

THE MECHANISM AND MANAGEMENT OF HEMORRHAGIC DISTURBANCES IN INFANCY AND IN CHILDHOOD*

By I. NEWTON KUGELMASS, M.D., NEW YORK, N. Y.

THE management of a hemorrhagic disturbance depends upon the nature of the systemic disease with which it is associated. Few bleeding problems are primary clinical entities, and few indeed are typical text-book pic-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., on May 25, 1932.

Between the two or three well defined hereditary diseases and the limited number of clear-cut hemorrhagic syndromes are the great majority of transitional hemorrhagic disturbances encountered in infancy and in childhood. We have differentiated them first in terms of either blood clotting or vascular dysfunction; and subsequently in terms of the determining factor controlling

the hemorrhagic picture.

The hemorrhagic status of a patient is best evaluated clinically in terms of degree of function of the vascular endothelium and of the blood. Although chemical changes are present in both blood and vascular systems in most hemorrhagic disturbances, the one or the other necessarily dominates the picture. It is only in truly hereditary hemorrhagic disease that absolute deficiency in the vascular system or in one of the clotting components is characteristically individual in its pathogenesis. But the number and variety of acquired hemorrhagic diseases are legion. They are necessarily characterized by varying degrees of functional change in the blood channels as well as in the blood clotting components expressed by the equilibrium relationship:

Reticulo-endothelial System

Blood

Vascular System

Typical hemorrhagic problems are therefore limited, while the majority reveal varied transitional changes in vascular phenomena and clotting components. But one or the other of these factors will constitute the controlling factor, and its determination is indispensable amongst the criteria essential for final diagnosis. Clinical symptoms alone never suffice for arriving at the exact nature of the underlying condition productive of the hemorrhagic disease. Besides the family history, the past hemorrhagic status, the constitutional susceptibilities, the nutritional regimen, the physical examination, the current therapy, and the blood picture, several simple tests are made for the determination of blood clotting and vascular function.

DETERMINATION OF VASCULAR AND BLOOD CLOTTING FUNCTION

(1) Blood Count. The blood picture reveals the degree and character of an anemia. While the severest acute or chronic anemias, even to the extent of one million red cells and ten per cent hemoglobin, are never productive of active hemorrhagic diseases, the differential count must nevertheless be carefully studied to rule out the presence of reticulo-endothelial disease. A case in point is that of a girl of eleven years who was admitted with the diagnosis of thrombocytopenic purpura because of a severe anemia, some purpura, a white count of 2,000, and platelets of 100,000. The child's condition was diagnosed by other clinical signs of leukemia, corroborated by findings of pathological myeloblasts.

(2) Platelets. Blood platelet deficiency is the commonest cause of pathological hemorrhage. Platelets are indispensable for thrombus formation and clot retraction involved in bringing about closure of bleeding vessels and cessation of hemorrhage. They vary not only in quantity but also in quality. Therefore they are counted from the plasma not only after the red cells settle, but

also at the end of an hour in a paraffin tube to determine the number remaining after agglutination. Normally half clump within the hour; but in thrombocytopenic purpura, the rate of agglutination is diminished and in hemophilia clumping hardly occurs at the end of an hour as a result of their marked stability.

The resistance of platelets may also be determined by the fragility test. Blood is centrifuged slowly to precipitate the red cells above which platelets are formed. A drop of the platelet suspension is added to each tube of a series of saline solutions of concentrations varying from 0.25% to 0.5%. Normal platelets begin to autolyze at about 0.38%, while hemophilic platelets remain resistant to hypo- and hypertonic salt solution. The morphology of blood platelets studied in smears reveals in addition changes in their quality.

smears reveals in addition changes in their quality.

(3) Clotting Components. The concentrations of the substances involved in the clotting process are collectively indicative of the blood clotting function. The ratio of the concentrations of the clotting substances,—fibringen, prothrombin and effective plaletets,—over antithrombin has been defined by us as the index of blood clotting function. This involves the additional determination of these substances which are invaluable in arriving at the diagnosis of difficult latent or active hemorrhagic problems. Drs. Bancroft and Stanley-Brown have found the determination of the index of blood clotting function a valuable preoperative guide to potential thrombosis, uncommon, of course, in children.

(4) Coagulation Time. Blood elotting time is no criterion of the hemorrhagic status of a patient. It may be normal though spontaneous bleeding be present as in purpura or jaundice; and be delayed though there be no hemorrhagic disease. The determination of the clotting time of blood passing through skin is certainly no indication of what might be expected in the operative field of other tissues. All injured tissues as well as shed blood dissociate into coagulating substances. The tissue factor may frequently be eliminated by determining the clotting time by veniouncture.

(5) Clot Retraction. Blood platelets definitely cause retraction of a clot with the expression of blood serum. It is exceptional to find a clot to retract in thrombocytopenic purpura. The blood used for the clotting time determination is observed at intervals for retraction, preferably in a watch-glass. Normally it begins within 30 min-

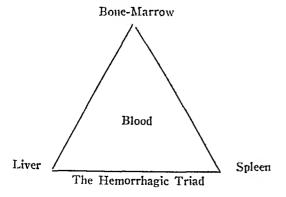

utes and ends within 4 hours.

(6) Bleeding Time. This empiric test done upon the ear lobe repeatedly is characteristic of thrombocytopenic purpura when prolonged. It does not parallel the number of platelets, although it is prolonged in diminished or absent clot retraction. The bleeding time is normal in hemoplilia because an injury precipitates sufficient platelets to plug the capillaries.

(7) Capillary Resistance. The tourniquet test determines the condition of the capillaries. Within a few minutes after the removal of the tourniquet the test is considered positive when a profuse crop of petechiæ appear at the site of the arm compressed by the tube. The rubber tourniquet is more valuable than the sphygmomanometer in making this test in hemorrhagic diseases.

Diagnosis and Treatment of Hemorrhagic Diseases

Disturbance in Blood Clotting Function. The hematic group constitutes the essential hemorrhagic diseases—hemorrhagic disease of the newborn, hereditary hemophilia, thrombocytopenic purpura, and the diseases of the bone-marrow, spleen, and liver. Each is characterized by a functional deficiency in one of the clotting components as the controlling factor in the pathogenesis of the hemorrhage. Each clotting factor congenitally deficient is indicative of a specific hereditary hemorrhagic disease. Each disease is amenable of control to the extent that the deficient factor is replaced or regenerated. Bleeding in these cases tends to be prolonged and continuous once the vascular integrity is disturbed. But until the provoking condition precipitates bleeding, many of these and associated conditions constitute potential hemorrhagic disease which determined not by symptomatology but by accidental study of blood clotting function.

Potential Hemorrhagic Disturbances. Bleeding is not an infrequent symptom of apparently well and active children. To be sure trauma, infection, drugs, and even insect bites induce all forms of benign hemorrhagic manifestations apart from hemorrhagic disease. But there is a group of well children in whom nose bleeds, black and blue spots, and other hemorrhagic manifestations are either indicative of potential hemorrhagic disease, or more generally of diminished blood clotting function, since the vascular endothelium suffers no disturbance in nutrition in severest anemia or hydremia. The physical examination may be negative, and the clotting time prolonged or normal, but yet the clotting components may

be diminished in prothrombin, fibrinogen, or platelets. We have observed in the last five years that these clotting components may be altered by dietary regimen.

Protein and fat tend to increase the concentration of the blood-clotting components, while carbohydrates and minerals tend to decrease them. We have therefore devised a "clotting diet" high in protein and fat, acid forming, low in vegetables and carbohydrates; and a "bleeding diet" high in vegetables, carbohydrates and water, base forming and, of course, minimal in protein and fat. The effect of these diets upon the clotting function has been demonstrated in animals to shift in the direction of an increase in either bleeding or clotting of the blood after a week of such a regimen. Similar results attain in children whose tendency towards bleeding is discovered accidently or preoperatively. Our surgical staff has been particularly concerned about the application of these dietaries preliminary to operations in order to prevent postoperative bleeding in some and thrombosis in others as predetermined by the index of blood clotting function.

Hemorrhagic Disease of the Newborn. Melena is a self-limited symptom-complex distinct from other hemorrhagic disturbances in the newborn. It is a transient though severe reaction of the newborn to chemical injury of the reticulo-endo-Its manifestation of bleeding thelial system. from the mucous membranes may simulate veritable diseases—syphilis and sepsis during the first days and purpura, hemoglobinuria and visceral anomalies during the first weeks of life. But the mechanism of melena is less deep-scated, and is self-compensating and even preventable. Potential hemorrhagic disease may be recognized the first day of life by means of the prolonged clotting time. This reveals injury in the formation of the blood clotting substances—prothrombin or fibrinogen. Their diminution is brought about by anesthetic drugs administered during labor, and by post-natal hemolysis of red cells, as well as by prenatal protein and fat deprivation on the part of the mother.

Though a multiplicity of factors may be operative in the development of melena neonatorum, the injection of 30 c.c. of human blood intramuscularly from the first day of life arrests oozing within 24 hours. But we have observed in the course of our studies of the nutrition of the newborn that the oral administration of gelatine from birth is preventive of hemorrhagic disease of the newborn. The feeding of 6% gelatine solution at 2-hour intervals has reduced the average clotting time of newborns from 9 minutes to 2 minutes in about 200 babies. We have not observed a single case of hemorrhagic disease of the newborn throughout the year during the administration of this modified solution primarily devised for the purpose of preventing loss of weight in the newborn. But several cases of active hemor-

rliagic disease of the newborn with low prothrombin or fibrinogen content of the blood observed in other hospitals have responded favorably to

gelatine feeding.

Prenatal prevention of potential hemorrhagic disease in the newborn is another approach. We have been privileged to observe cases of recurrent melena neonatorum in babies born of the same mother, T. N., under the obstetrical care of Dr. Tritsch at the Fifth Avenue Hospital. The first four pregnancies terminated in death from hemorrhagic disease as substantiated by postmortem examination. It was during the fifth pregnancy that a prenatal attempt was made to prevent the anticipated severe melena. mother's blood showed a concentration of clotting components characteristic of hemorrhagic disease in the newborn. She was put on a very high protein dietary in contrast with her usual low protein intake which had been limited during previous pregnancies because of hypertension. Her blood clotting picture became adequate and a normal infant was delivered at term. baby has been under my observation for four years and has been perfectly well since birth. Encouraged by her favorable fifth pregnancy she proceeded to a sixth but refused to be under rigid nutritional supervision and was delivered of an infant with melena proven by the postmortem examination in the same institution.

Essential thrombocytopenic purpura is a benign disease of the reticulo-endothelial system. Its site is primarily in the spleen where platelets are destroyed; and secondarily in the bone-marrow where lesions interfere with normal platelet formation. The marked reduction in the number of blood platelets and their alteration in size and structure bear no definite relationship to the severity of the bleeding, the bleeding time, the impaired clot retraction, and the diminished capillary resistance. But this blood picture appearing suddenly in an apparently well child without discoverable cause for the hemorrhagic state and the presence of post-hemorrhagic anemia and leucocytosis, determines the diagnosis. These eriteria characterize the disease in all grades of severity-in the acute fulminating type, in the transient attack, and in the chronic latent course, whether the bleeding be limited to a single source or be widespread.

Effective control of bleeding in acute cases, or prevention of bleeding in the chronic problems, depends upon procedures for increasing the concentration of blood platelets. All other methods are wasteful and without effect. In emergencies, the intramuscular injection of 50 c.e. of whole blood requiring no typing, increases the platelets and arrests hemorrhage. But large transfusions from a suitable donor not only supply platelets, but actually stimulate platelet generation. They must be repeated every fourth day paralleling the average life of infused platelets, High fat feed-

ing rich in vitamin D, and ultra-violet irradiation, particularly after anointing the body with wool fat, produce transient rises in platelets and help tiding over an acute problem.

Persistent bleeding in 70% of chronic cases is permanently relieved by spenectomy. It is unfavorable in acute conditions where the mortality is 80% in comparison with 8% in the chronic cases. The operation must be properly timed for obtaining favorable post-operative prognosis. Preliminary roentgen irradiation of the spleen produces a leucopenia which is an unfavorable prognostic omen. Splenic enlargement is no necessary criterion for operation, although the removal of massive spleens has saved lives from uncontrollable hemorrhage. Following splenectomy the platelets may rise to a million and then return to normal levels in patients in which platelet destruction has been the mechanism. But in those in whom platelet formation has been retarded, the post-operative rise in platelets is less marked and the subsequent level attained is necessarily low.

Symptomatic thrombocytopenic purpura. Purpura is a hemorrhagie symptom widespread amongst many diseases. Besides the essential type it may be a manifestation of clinical syndromes associated with diminution in blood platelets in diseases of the bone marrow, spleen, and reticulo-endothelial system as a result of infeetion or intoxication; or it may be a symptomatic expression of mere capillary injury in the course of systemic infection, chemical intoxication, allergic offense, and a variety of other capillarytoxic conditions. In one group of conditions the blood picture is a revelation of blood cell injury; whereas in the other group the blood picture is usually normal. Purpura therefore becomes primarily a problem for careful clinical differentiation between the varied types of diseases characterized by either clotting or vascular dysfunc-That diagnostic differentiation makes all the difference between benign and malignant diseases, effective and fancied therapy, favorable and fatal prognosis.

Treatment of symptomatic thrombocytopenic purpura necessarily depends upon the primary diseases. Splenectomy is indicated in Gaucher's disease and in constitutional hemolytic anemia because the purpuric mechanism is similar to that of essential thrombocytopenic purpura. But the great variety of other conditions are the result of destruction of blood-forming organs by intoxication, infection, or infiltration resulting in malignant thrombocytopenia. Some infectious diseases injure specifically the megakareocyte mechanism. Primary blood diseases in addition affect the formation of other blood cells. Certain drugs likewise reduce myeloid elements of the blood. These myelotoxic conditions are malignant, resisting all forms of therapy. But the associated vascular injury and infiltration may be influenced to arrest

bleeding. Stryphnon is an effective local hemostatic in that it is a stable intermediate product preceding epinephrine formation with more striking vasoconstrictive properties. Slow intravenous injection of 10% calcium gluconate or chloride daily in 20 c.c. amounts, supplemented by oral administration of calcium salts, are transient therapeutic measures alternated with transfusions. But splenectomy is contraindicated.

Purpuric problems Comment. rarely patterned text-book pictures. Only purpuric children illustrate how strikingly borderline diagnostic criteria may be. Dr. L. Marton's eight-year boy developed a characteristic thrombocytopenic purpura with remissions until splenectomy became imminent. Then he came under my observation only to find that he had been quantitatively deprived of protein and fat because of a chronic eczema. As a last resort a high protein and fat dietary brought the platelets from 20,000 to 400,000 with the disappearance of purpura since 1927. Obviously I am not advocating dietary specificity in thrombocytopenic purpura.

S. T. was admitted as a thrombocytopenic purpura with severe bleeding from the gums for five months, but without other hemorrhagic symptoms. Hemoglobin was 28%, red blood cells 1,200,000, white cell and differential count normal. Platelets 40,000, tourniquet test positive. Systemic treatment of a severe Vincent's infection, and transfusions, cleared the problem for which splenectomy was, of course, no indication.

N. K., a five-year boy developed hemorrhagic otitis media epistaxis and hematuria following tonsillectomy at 3 years of age when clotting and bleeding time determinations were normal. Purpuric symptoms recurred for two years until admission to the hospital. Clotting and bleeding time were normal; tourniquet test negative; platelets 35.000; white cell and differential count normal; spleen not palpable. On a clotting dietary the platelets rose to 240,000 but fell again with remission of symptoms. Splenectomy brought the platelets to 415,000 with recovery.

M. S.. a girl of eleven years, was admitted with repeated and severe epistaxis for a week. Epistaxis and excessive bruising appeared periodically for two years requiring medical care. Clotting and bleeding times were normal. Tourniquet test negative. Platelets 110,000. Spleen not palpable. Blood picture normal. Consensus of opinion was against splenectomy; but that was performed as an emergency procedure in another hospital under unfavorable conditions of uncontrollable hemorrhage four months later with subsequent recovery.

Hemorrhagic Diseases of the Liver. Hemorrhagic manifestations are frequent concomitants of many of the diseases of the liver. Congenital obstruction of the bile ducts, infectious destruc-

tion of the liver parenchyma, and chemical poisoning, frequently result in hemorrhagic symptoms. They are the result of both fibropenia and vascular injury. Fibrinogen deficiency is the common blood-clotting factor controlling the hemorrhagic picture in disturbances of liver function. Bile acids have been associated with the cause of the bleeding; but their concentration rarely reaches a sufficient level to dissolve the formed clot, nor does the intensity of the jaundice parallel the severity of the hemorrhages. Frequently hemorrhagic symptoms are present in liver disease without jaundice as an associated condition.

Hemorrhagic symptoms have also been associated with a deficiency in the available calcium in the course of jaundice because of a hypothetical combination of calcium with bile acids. The blood calcium is normal in liver diseases and plays no determining role in the hemorrhagic symptomatology. To be sure calcium therapy diminishes bleeding, but that effect is upon the vascular system and not upon its blood content. Both hemorrhagic symptoms and cholemia are simultaneous expressions of disturbed liver function induced by the same toxic factor; and one symptom is not necessarily related to the other, but rather to the common cause of the liver disease.

Fibrinopenia is a hemorrhagic syndrome associated with diseases of the liver. It is characterized by markedly prolonged clotting and bleeding times, markedly diminished fibrinogen content, and a normal platelet count. Even in extreme degrees of the failure of the blood to clot there is no evidence of vascular injury in the noninfectious types of liver disturbances. obstructive jaundice the bleeding disturbance is the result of alimentary toxic substances accumulating in the liver, and producing capillary injury. Hemorrhagic manifestations are never observed in catarrhal jaundice or in gall stone formation; but are present in 40% of the cases of acute yellow atrophy, and in 90% of the cases of cirrhosis of the liver, and in all cases of chloroform and phosphorus poisoning. These are rarities in children in this country.

HEREDITARY HEMORRHAGIC DISEASES OF BLOOD CLOTTING DYSFUNCTION

Hereditary hemophilia is a clinical chimera for many a bleeding problem. It is too rare a condition to cover so many hemorrhagic disturbances, and is too well-defined an entity to become a haphazard label of hemorrhagic confusion. Bulloch and Fildes have been able to authenticate only 44 hemophilic families out of 273 reported in a century of literature since its classical description by Otto in 1803. The disease occurs exclusively in the male with a typical familial bleeding pattern, and must not be confused with other familial hereditary hemorrhagic diseases

afflicting females. It is transmitted through the female, although the mothers of our hemophilic boys showed normal blood-clotting function. It is characterized by prolonged duration of bleeding even though the clotting time often be only slightly prolonged. It paradoxically shows a normal bleeding time, because the skin-clotting function is greater than that of mucous and scrous membranes. Hemophilic blood shows the lowest index of blood clotting function with normal, or increased number of platelets physiologically defective, because of their strikingly great resistance.

Case Comment. Diagnostic criteria are not always clear-cut in transitional hemorrhagic problems

C. M., a 2-year boy, showed no bleeding tendency until many bruises appeared following trauma incident to walking at eleven months of age. No family history in 3 preceding generations. Clotting time 6 minutes but clotting index 0.009, when the blood picture otherwise was normal.

D. B., a 6-year boy with hemophilic joints, clotting time 11 minutes, bleeding time 18 minutes, normal platelets, positive tourniquet test, normal clot retraction. Father allergic. A hemophilic with athrombopenie purpura.

G. M., a ten-year boy, required repeated blood transfusion following slight traumata since birth. He was under my observation for a hemophilic arthritis 2 years ago. But recently he developed broncho-pneumonia with otitis media precipitating spontaneous bleedings from nose and gums. Clotting time, 10 minutes. Bleeding time 13 minutes, platelets 60,000, spleen enlarged, tourniquet test negative. A transient purpuric picture in a hemophilic.

B. S., a 9-year boy, was admitted as a "hemophilic" after three hospitals refused tonsillectomy because of prolonged clotting time. Hemorrhage first occurred after myringotomy in infancy. Slight bruising followed slight trauma. No family history of hemophilia. Clotting index 0.2, increased to normal by a "clotting" dietary. Tonsillectomy was performed without post-operative bleeding.

Hemophilic bleeding can be controlled but not cured. Mild bleeding may be stopped locally by applications of fresh raw meat, fresh blood, or cephalin, after the removal of useless clots, since pressure alone is contraindicated. All other hemostatics locally applied are ineffective. Severe bleeding may be checked for four days by the transfusion of whole blood from a suitable donor. Even an ounce of injected blood arrests hemorrhage; but the degree of subsequent improvement depends upon the blood given. Stored serum is ineffective in inhibiting clotting, but an ounce of fresh serum arrests bleeding within a day.

But protein sensitization is beneficial in diminishing bleeding from superficial injuries as well as in abating recurrences. The child is sensitized to horse serum by subcutaneous injection of 3 c.c. of seruin. We have seen no difference between the use of diphtheria and antivenim serum. At the end of a week the child is given 2 minims injected intradernially which shows successful sensitization by the wheal formation. Intradermal injection should be repeated monthly for the maintenance of sensitivity, an effect primarily upon the capillary system. The treatment is helpful in hemophilie arthritis for which autogenous blood has also been given intramuscularly. Obviously the sensitization mechanism is the same. It increases the recession of the hemorrhagic joint which must be immobilized in a neutral position by means of plaster casts when necessary.

The prevention of hemophilia is a problem for cugenics. The course of the disease can be altered. Nature spares hemophilic newborns from the effects of birth trauma by the transmission of an abundance of female sex hormone into the infant's circulation. Thus it is that the disease does not become manifest until late in infancy unless surgical intervention precipitates bleeding. The disease tends to ameliorate with growth, particularly after the endocrine adjustment of puberty. The absence of the female sex hormone in hemophilics has made its isolated preparation a therapeutic indication. We have found that the injection of female sex hormone preparation. alone or reinforced by anterior pituitary extracts, produces no change in the concentration of the clotting substances from the levels characteristic of hemophilics. But we have observed that 500 mouse units of the hormone are necessary to increase the capillary resistance sufficient for it to reveal a negative test within two days in hemorrhagic diseases affecting vascular integrity rather than the blood clotting content.

Our hemophilic boys with joint manifestations have benefited most during the year in that the periodic effusions were diminished. The hormone therapy has not diminished the tendency to bruising, but has decreased the tendency to bleeding following natural trauma. The avoidance of trauma by limitation of activity requires compensatory physio-therapy measures for improving muscle tone. The maintenance of bodily warmth and vacationing in warm climate appear in addition to alter favorably the course of the disease. Our clotting dietary has produced no appreciable effect upon the hemorrhagic status of hemophilia. Infection has been found to precipitate bleeding particularly into the skin and joints. Operative emergencies are safely carried out after preliminary transfusion.

Hereditary thrombosthenic purpura. Typical manifestations of thrombocytopenic purpura may be simulated by an hereditary purpura involving strikingly abnormal and functionally inactive platelets. It is a familial defect transmitted from generation to generation to both males and females. It is readily differentiated from hemophilia in this respect as well as in the blood picture. The number of platelets fluctuate in different members of these families from relatively low normals to high values. But abnormalities in their size, shape, staining qualities and failure of agglutinization is a characteristic common to all. As a consequence the bleeding time is prolonged, the clotting time is normal, the clot retraction retarded, the tourniquet test positive, the spleen rarely enlarged and purpuric bleeding is a common sympom.

Case Comment. Such was the case of a tenyear girl who continued to bleed excessively despite splenectomy performed on the basis of a supposed chronic thrombocytopenic purpura. She had recurrent epistaxis and purpura since the first year of life. The mother, a mild bleeder, died The son is not a bleeder. during childbirth. Child admitted to a N. J. hospital in emergency. Pre-operative blood picture—hemoglobin 60%, red blood cells 3,200,000, white blood count 17,000, polys 80%, lymphocytes 8%, monocytes 6%, platelets 350,000, lysis 12%, tourniquet test negative, clotting time 10 minutes, bleeding time 15 minutes, clot retraction absent. Transfusion effective. Vascular therapy without avail.

B. Disturbances in Vascular Function. bleeding problems of the vascular group are, strictly speaking, non-hemorrhagic diseases. The blood of each disease shows no abnormality in clotting function but the disease is a dysfunction of the capillaries. The vascular changes are produced in one of several ways—softening of cement substances binding endothelial cells, injury of the living cells, destruction of elastic fibers, disturbance in innervation for normal contractility of vessel walls. The bleeding disturbances are spontaneous, and single or multiple, but with little tendency towards continued bleeding. The bleeding in each of these diseases is better tolerated than in those of abnormal blood con-The transient injury to the capillaries becomes manifest in extravasations of blood as in scurvy, and Schoelein's and Henoch's diseases on the one hand, and by blood combined with inflammatory exudations as in severe infectious diseases and in chemical poisoning, on the other. Effective treatment of the heterogenous group depends upon the administration of substances to decrease capillary permeability immediately while the controlling factors are being corrected.

Avitaminosis. Vitamin deficiency results in degeneration of the capillary endothelium. Scurvy is the classical example of the specific relation of vitamin C deficiency to the extravasation of blood under the periosteum and in the deep muscles, into the skin, mucous membranes and around

hair follicles. Infection accentuates vascular injury. Aschoff demonstrated separation of cement substances binding vascular endothelial cells. The blood-clotting function is normal excepting for the positive tourniquet test which is indicative of capillary injury. In severe cases there are changes in the bone marrow with interference in the myeloid activity causing a diminished platelet formation. But the initial vascular phenomena control the clinical picture of scurvy in children.

Vitamin B¹ (or F) deficiency has likewise been demonstrated to injure the vascular endothelium to the extent of producing hemorrhagic manifestations. There is evidence that deficiency of this vitamin in the diet of the pregnant woman is one of the factors responsible for hemorrhagic disturbances in the newborn involving vascular injury. Hemorrhagic manifestations definitely associated with avitaminosis have been observed in the course of marasmus and Herter's infantalism. The nutrition of the vascular endothelium evidently depends in part upon vitamin adequacy, and the minutiæ of nutrients; while blood content in clotting substance depends upon the gross nutrients, protein, and fat.

Allergic purpura. Recurring symptom-complexes of the skin, joints or intestines reveal purpuric spots. Cutaneous eruptions with erythema, urticaria, agnionemotic edema as well as purpura constitute erythema multiforme. Mild arthritis with pain, tenderness and swelling of the joints of the lower extremities clustered with purpuric spots constitute Schoelein's purpura. Attacks of colic with abdominal pain, tenderness and rigidity, purpuric spots over the skin, blood in the vomitus, urine and stool constitute Henoch's purpura. The blood clotting function is normal but for the positive capillary resistance test. heterogenous group of syndromes has a common allergic basis in that increased capillary permeability is suddenly produced by certain foods or bacterial toxins in allergic children.

Treatment involves clearing of the infection and simultaneous elimination of the allergic offense. Intestinal disinfectants, colonic irrigations, belladonna suppositories, protein desensitization, ephedrin administration, salicylate medication, intravenous saline, and calcium therapy are the effective procedures. Injection of foreign protein results in violent reactions, transfusions are unnecessary and splenectomy of course out of order.

E. M., five years of age, the daughter of a physician, was presented with purpuric spots over the lower extremities. There was great anxiety about threatened splenectomy. A year ago the child had a severe tonsillitis with associated pain in the abdomen, knees, and legs. After subsidence of the fever a tonsillectomy was performed on the basis of supposed rheumatic fever. But after the operation purpuric extravasations and petechiæ appeared over the legs. No such mani-

festations appeared until this winter when a similar syndrome recurred with each upper respiratory infection. Attacks of urticaria and ecchymoses alternated or appeared simultaneously. The child was admitted to the hospital for study as a case of allergic purpura. Platelets 385,000, tourniquet test positive, clotting and bleeding time normal. Father and patient allergie. Bacterial desensitizations in progress.

A. W., a girl of twelve, with similar symptomatology was seen in consultation during an attack which simulated gastric ulcer. Hematemesis, abdominal pain, epigastric tenderness clouded the clinical picture. Blood picture and gastro-intestinal series were negative. During convalescence deep intramuscular hemorrhages prolonged the pain and tenderness of the lower extremities.

Hemorrhagic Infectious Diseases. Hemorrhagic symptoms predominate in infectious invasion. Vascular injury usually exceeds the disturbances in myeloid function but the relative changes in each depend upon the severity of the infection. We have observed petechiæ containing the organisms in meningicoccemia, embolic abscesses with visceral hemorrhages in pneumococcemia, nose bleeds; and even hemorrhagic sputum in epidemic influenza, thrombotic petechiæ consisting of tuberculosis, punctate hemorrhages in scarlet fever, mucous membrane bleeding in diplutheria, hemorrhages from the mucous membranes in congenital syphilis and purpura associated with the presence of endothelial cells in circulating blood of subacute bacterial endocarditis confirms vascular injury.

Capillary hemorrhages are not infrequent as consequences of vascular congestion in the course of chronic infections. Rheumatic heart disease induces epistaxis or congestion hemorrhages in the lower edematous extremities. Pertussis prediction in the conjunctive, eyetimester in the lower edematous extremities. Pertussis prediction in the conjunctive, eyetimester in the conjunctive, eyetimester in the conjunctive, eyetimester in the conjunctive in the conjunctive in the conjunctive in the morrhagic symptoms in uremia parallel the severity of capillary damage from infection and not the degree of nitrogenous retention. Increased venous pressure in normal circulatory systems is not a determining factor in these bleeding manifestations.

Arrest of bleeding in the course of infectious invasion may be brought about by therapeutic measure for decreasing capillary permeability. Eltimination of infection is of course the primary concern, but the self-limited nature of infectious disease necessarily requires vascular medicaments. Clinically, calcium salts have been used in most hemorrhagic diseases for centuries with favorable effect, but based upon erroneous interpretations. The calcium required in the clotting mechanism is rarely found wanting in amounts necessary for this process. Even the striking clinical entities

involving hypocalcemia never reveal bleeding symptoms.

Calcium therapy is indicated in abnormal bleeding resulting from vascular dysfunction. Its effect is specific in decreasing capillary permeability. The calcium salts administered have no bearing whatever upon elevating the well buffered calcium content of the blood. Calcium therapy is best administered intravenously in a 10 per cent solution of calcium gluconate, or calcium cultoride, from 10 to 25 c.c. injected very slowly. Oral administration is, of course, slower in its effect but may well be supplemented in 5 to 10-grain doses offered between feedings to prevent its precipitation in the intestinal tract and subsequent loss in the stool.

Gelatine administration arrests bleeding by condensing platelets upon the vascular bed. It may be injected intravenously in 10 per cent solution from 20 to 40 c.c. or fed in 10 per cent solution either directly, sweetened and flavored with vanilla or mixed with milk or as a jeily which

may be kept on ice for two days.

Pituitary extracts of the postcrior lobe are effective vasoconstrictors in arresting bleeding. This mechanism is operative in vascular beds other than those of the female genital organs. The injection of 0.5 c.c. of pituitrin frequently suffices to arrest capillary oozing when due to vascular injury. The action is more prolonged than that of adrenalin. It is the vasopressor fraction of the postcrior lobe which affects the vascular endothelium in the direction of increased blood coagulation.

Diet affects the hemorrhagic status of patients even in the course of severe infection. It tends to increase the blood-clotting components to the extent of producing a thrombotic picture. And yet bleeding from mucous membranes may be present because of embolic phenomena associated with the vascular injury. Therefore the dietary indicated is for reduction of the increased coagulability of blood. This is attained by fruits, vegetables and carbohydrates with the exclusion of proteins and fats.

Clinical Comment. H. R., a four-year boy, was admitted to the hospital with a history of convulsions associated with a severe upper respiratory infection. Hemorrhage appeared in the orbit and marked purpuric extravasations over trunk and upper extremities. Facial weakness and complete right hemiplegia followed. Spinal fluid negative. Clotting and bleeding time normal, tourniquet test positive, platelets 310,000, platelet lysis 35%, blood clotting function normal. Encephalitis infection causative of purpura.

N. C., a five-year boy, developed recurrent severe epistaxis in the course of osteomyelitis with septicæmia. The blood clotting function was five times normal with platelets ranging around 1,300,000 per e.e. and yet vascular injury as a re-

TABLE I

sult of the infection was not compensated by the thrombotic blood picture. On the other hand, we have seen no hemorrhagic symptoms nor angina in B. S., a boy of eight, with lymphatic leukemia and a platelet count as low as 40,000. It is folly indeed to ever relate the hemorrhagic status to one factor alone.

Hemorrhagic Chemical Intoxications. Chemical poisons destroy the capillary endothelium producing hemorrhagic symptoms. The toxic effect is not only upon the vascular system, but also upon bone-marrow function. All poisons, organic or inorganic, accidental or therapeutic,

cause marked degeneration of vessel walls. Effective therapy depends upon the diagnosis and climination of the chronically ingested drugs, accidental or therapeutic. Salicylates or atophan displace some of the toxic drugs. Continuous injection of intravenous saline solution slowly eliminates the circulatory content in chemical poisons. Calcium therapy arrests bleeding by its effect on capillary permeability. Repeated transfusions accelerate clotting function and improve the anemia. The prognosis is not favorable because of the irreversibility of chemical destruction of bone-marrow and vascular bed.

TABLE II
BLOOD COMPOSITION ON SUCCESSIVE BLEEDING AND CLOTTING DIETS

Dog	Diet	Prothrombin Normal =1	Fibrinogen Normal =05	Antithrombin Normal = 1	Platelets Normal =250,000	Index Normal =0.5
1	Normal	1.11 1.11 1.45	0.64 0.64 1.12	1.16 1.16 0.96	200,000 200,000 250,000	0.6 0.6 1.7
2	Normal	1.00	0.54	1.00	400,000	0.5
	Carbohydrate and vegetable	0.74	0.54	1.00	220,000	0.3
	Protein and fat.	1.00	0.64	1.00	300,000	0.7
3	Normal	1.11	0.64	1.16	220,000	0.6
	Carbohydrate and vegetable	1.11	0.28	1.00	135,000	0.3
	Protein and fat.	1.26	0.69	1.00	210,000	0.9
4	Normal	1.00	0.40	1.16	200,000	0.3

Mother's blood showed a deficiency in prothrombin and fibrinogen early during her filth pregnancy. Normal haby at term following maternal clotting dietary. Sixth newborn without prenatal supervision resulted in fatal hemorrhagic disease similar to first four newborns

Hereditary Telangicciasis Puberty first precipitates bleeding varicosities in this congenital developmental defect. It is characterized by an inherited deficiency in venous channels in the buccal and masal inucous membranes, facc, cheeks, cars lips, tongue, although other parts of the body may be involved. The telangicciases vary in size from a pinpoint to a pea and may be flat or raised. Bleeding from these dilated vessels is often severe and may even be fatal. The condition is unnecessarily confused with purpura and hemophilia for the blood is normal.

SUMMARY

1 Hemorrhagic disturbances are syndromes associated with many disease and produced by varied causes

TABLE VIII
THERAPEUTIC MEASURES FOR THE ARREST OF BLEEDING

ļ	CHAR	ACTER OF THE DE	SEASE	
Procedure	Platelet Deficiency	Fibrinogen Prothrombin Diminution	Vascular Disturbance	
Local	Coagulen Ultraviolet Irradiation	Thromboplastin Meat Juice	Stryphnon Styptysate	
Oral	Viosterol	Cephalin Fibrinogen	Calcinm Salts	
Nutritional	Dietary Fat (Unsaturated Lipids)	Dietary Protein (Gelatine Viscera)	Base- forming Foods	
Intramuscular	Foreign Protein	Blood Serum	Pituitrin Parathormone	
Intravenous	Transfusion	Transfusion	10% Calcium Salts 10% Gelatine	

- 2 Clinical examination must be correlated with the blood picture in arriving at a diagnosis of hemographic disease
- 3 Methods are presented for the determination of the hemorrhagic status of a patient in terms of degree of function of the vascular endothelium and its blood content
- 4 Hemorrhagic problems are rarely patterned text book pictures although a clotting component or a vascular alteration determines the control ling factor diagnostic of the disease
- 5 Potential hemorrhagic disturbances reveal a low index of blood clotting function improved by a dietary high in protein and fat
- 6 Potential hemorrhagic disease of the newborn may be prevented by the oral administration of gelatine solution and prenatally by a "clotting dietary"
- 7 Diagnostic differentiation with appropriate therapy is given critically for problems of throm-bocytopenic purpura
- 8 Bleeding associated with diseases of the liver is interpreted on the basis of disturbed liver function
- 9 Hemophilia, a clinical chimera for abnormal bleeding problems, can be definitely diagnosed and controlled therapeutically
- 10 Abnormal bleeding resulting from vascular injury constitutes non-hemorrhagic disease characterized by normal function of the blood clotting mechanism
- 11 Avitaminosis results in degeneration of vascular endothelium observed in scurvy, maras mus and Herter's infantalism
- 12 Allergic purpura is a symptom complex in volving the skin, joints and intestines previously designated as erythema multiforme, Schoelein's purpura and Henoch's purpura respectively

TABLE IX

CLASSIFICATION OF HEMORRHAGIC DISEASES IN INFANCY AND CHILDHOOD RESULTING PRIMARILY FROM BLOOD CLOTTING DYSFUNCTION

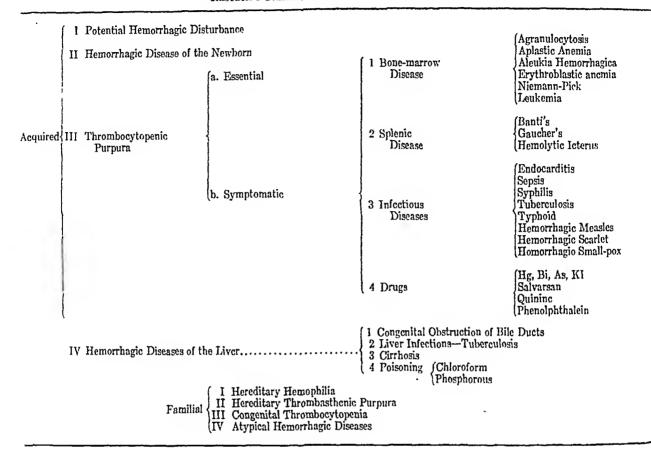

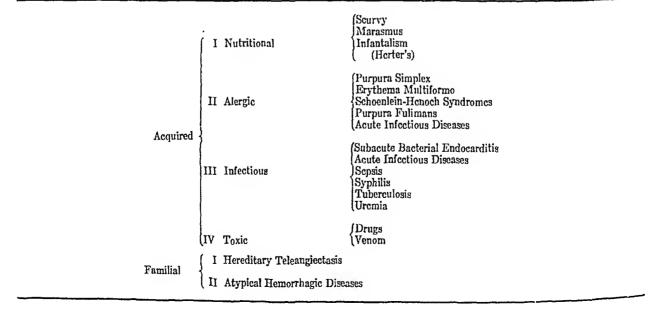

TABLE X

CLASSIFICATION OF HEMORRHAGIC DISEASES IN INFANCY AND CHILDHOOD

RESULTING PRIMABILY FROM VASCULAR DYSFUNCTION

13 Severe infections and chemical poisons are primarily capillary toxic requiring vascular medicaments for arrest of bleeding

14 Atypical hereditary hemorrhagic diseases involving deficiency in "clotting components" or

in vascular endotlichum still prevail without diagnostic characterizations

15 A clinical classification of liemorrhagic diseases is offered based upon alteration in vascular endothelium or its blood content

THE SIGNIFICANCE AND TREATMENT OF PYURIA IN CHILDREN By JAMES R WILSON, M D, SYRACUSE, N Y.

From the Department of Pediatrics, College of Medicine, Syracuse University, and University Hospital, Aided by the Hendricks Fund Read at the Annual Meeting of the Medical Society of the State of New York at Buffalo, N Y, May 25 1932

URING the past eleven years it has been my privilege to observe several hundred infants and children showing pus in the urine, and in more than 70 subjects, to study the changes occurring in the urinary tract at postmorten

In this paper I shall briefly present data on the pathology of so called pyelitis, certain new data relative to so called "recurrent pyelitis," and new data relating to the controverted point of the etiology of urcteral strictures. These and other observations illustrate the importance or the significance of pyinta and suggest the need of prompt recognition, adequate treatment, and in other cases, preventive measures.

These and other data suggest new values in the appraisal of the significance of pyuria and at the same time suggest principles underlying treatment

treatmen

Historical A brief historical review seems es sential to show the development of our concepts

The frequency with which the less severe forms of pyuria occurred was not generally recognized until the earlier part of Holt's generation. In 1887 and 1892 Holt called attention to the frequency with which pus occurred in the urine of infants. He reported several cases which he says were "published for the purpose of drawing more attention to the importance of the examination of the urine at this time of life something which heretofore has been overlooked almost entirely, except in cases of diphtheria and scarlet fever."

Interest in urine examinations was greatly in tensified following this period Excellent chin cal descriptions of the symptomatology were presented of what was then called "pyclitis" Be cause most of the children who suffered from pyuria recovered, opportunities for post-mortem study were few and the anatomic lesion was not established. For various reasons, however, the condition came to be looked on as an inflammation of the pelvis of the kidney. This erroneous view is perhaps one of the factors which has hampered the study of therapeutic procedures.

As time went on, the frequency with which

pyehtis was diagnosed clinically, however, presented a striking contrast to its extreme rarity it post-mortem. Many therefore, began to doubt the dependency of pyuria in the young on inflam mation of the pelvis of the kidney, but sought its origin in some other part of the urinary tract Among these were Themich, Bugbee, Chown, Schloss and Wilson

Thus it came about that the pathology associated with the condition ordinarily diagnosed

'acute pyehtis" was re investigated

Pathology of Acute Upper Urmary Tract Infections By such processes as have been briefly alluded to, a conception of the nature of so-called "acute pyelitis" came about During recent years, however, these older conceptions have been altered Our knowledge of the pathology of so called "acute pyelitis" in infancy is based principally on a study of material from three large Eastern pediatric clinics reported by Chown, Schloss and Wilson The nature of the pathologic processes involved in the majority of cases of so-called "acute pyelitis" in infancy may be briefly summarized in the following manner

The anatomic lesion is in the interstitial tissue of the kidney and is essentially pyogenic in character. In its earliest stages, the lesion is represented by minute foci of round cells and polymorphonuclear lcukocytes. These areas vary in number and are widely scattered and may involve some areas of the kidney to a greater degree than others. In more advanced cases the lesions are of larger size and may show necrosis

with definite formation of abscesses
In no case have we observed pyelitis as an iso-

an no case nave we observed pyelitis as an isolated lesion. Two of our post-mortem examinations disclosed inflammation of the kidney pelves, but in these inflammation of the interstitial tissue of the kidney was present and of more marked degree. The anatomic basis of so called "pyelitis" of infants is probably suppurative nephritis

It is not our opinion that pyuna in infants is always due to a suppurative interstitial nephritis. On the contrary, there are a number of other conditions to which it may be due, but in our

experience these are relatively rare. Cystitis occasionally occurs in infants. Renal calculi, although rare, may provoke pyelitis in early life. True pyelitis as an isolated entity is extremely rare, the only reported case being that of Cabot and Crabtree.

Such we believe is the underlying pathology of so-called "acute pyelitis" in infancy. In older children the pathology of the condition has not been definitely established as yet. This is due to the paucity of correlated clinical and pathological observations. The very meager data now available suggests, however, that fundamentally the

processes are similar.

Chronic Pyuria: We shall now turn to chronic pyuria. Why does so-called "acute pyelitis" become chronic? What are the factors which make a chronic case out of an acute one? It is generally recognized that when pyuria does not respond in the usual length of time and after the usual therapeutic measures have been vigorously prosecuted, that other factors are present besides those which produce a simple acute pyuria. Obstruction to the outflow of urine is believed by many observers to be the most common of these factors.

Hunner was among the first to point out the relationship between chronic pyuria and urinary stasis. Since his first report many others have

appeared.

Obstruction to the outflow of urine may occur at any point in the urinary tract. The most common site, however, appears to be in the urefers. Some enthusiastic workers have stated that ureteral strictures are responsible for 95 per cent of the cases of chronic pyuria in infancy and childhood. While we are not convinced that this degree of enthusiasm is warranted, we do feel that ureteral obstruction is very often of primary importance.

This brings us to the controverted point in which we are interested and on which we have additional data to present. What is the nature of ureteral obstruction in the young? In other words, what is the etiology of these ureteral

strictures?

There are two principal views. Certain observers believe that most of them are acquired—that they are the result of inflammatory processes. By others they are thought to be largely congenital. The fact that there is still room for controversy led me to investigate.

Ureteral Strictures: It was felt that a study of the urinary tracts in a series of very young individuals would throw some light on the subject.

This was done.

The urinary tracts in a series of 100 consecutive necropsies were subjected to particular study—the object being to study the nature and incidence of ureteral strictures.

Outstanding points in the data are as follows: Fifty-seven of the 100 subjects were under 1 month. Thirty-six were between 1 month and 1 year, and 7 were between 1 and 3 years old. Congenital urinary tract anomalies were observed in 13 of the 100 subjects. Narrowing of the lumen of the ureter and kinking were observed in 9 per cent. Urethral obstruction was observed once.

Ureters which on examination and dissection failed to permit the passage of a probe 1 mm. in diameter were classified as showing actual or potential evidence of obstruction. Dilatation of the ureter and pelvis above the lesion were considered still further evidence of obstruction. A considerable post-mortem experience among children, before and after the present study, has led to the belief that a normal ureter will permit the ready passage of a millimeter probe throughout the entire length—even at the physiologically narrowed sites.

Ureteral strictures were observed in 7 subjects. In 6 instances the narrowing of the lumen appeared to be an accentuation of the physiological narrow sites and in one instance, the obstruction was due to a twist in the ureter with the production of a valve. In 4 of these 7 cases the lesions were unilateral and in 3, bilateral. The ureter and pelvis above the lesion was dilated in 5 of the 7 subjects.

Ureteral kinks, which were firmly held in place by fibrous bands were observed in 2 additional cases but were unassociated with narrowing of

the lumen.

Ureteral strictures, or kinks of inflammatory

origin were not observed in this series.

It is our opinion, based on evidence set forth, that congenital defects are the most common cause of the strictures of the ureter in early life. The relatively large number of individuals showing definite or potential sources of obstruction make it unnecessary to assume, we believe, that inflammatory strictures are of frequent occurrence in childhood.

The work of Bigler, Schreiber, and others lends added support.

The finding of 7 per cent of strictures in our subjects is of great practical importance, particularly if generally true as we are inclined to believe it is. Pyuria, unaffected by the usual medical methods in a reasonable length of time and which does not respond to the removal of extrarenal inflammatory foci, should be subjected to a thorough investigation of the urinary tract. The repair of strictures and the return of a normal flow of urine goes a long way toward making it possible for nature to heal the inflammatory process above the site of obstruction.

Recurrent Upper Urinary Tract Infections: You are all familiar with subjects in which pyuria recurs at periodic intervals. What makes pyuria

recur periodically in certain subjects? Why is an individual more susceptible after once having suffered from an attack? Cases of the type about to be mentioned contain suggestive data.

A girl of 11 years entered the hospital with acute cervical lymph noditis, fever, and pyuria. On previous occasions she had suffered from recurrent attacks of pyuria with fever of the type ordinarily diagnosed "acute pyelitis." Between attacks of pyuria, her doctor stated that she was afebrile and the urine free from pus.

What was the inciting cause of this attack of pyuria? Of course, we cannot be sure, yet we feel that it was due to her upper respiratory infection and cervical lymph noditis. In any event, co-incidentally with the clearing up of her eervical lymph node infection the pyuria cleared.

The only treatment used in this case was rest in bed and fluids. The results were very satisfactory. Further study of this case revealed evidence of impaired kidney function, which after recovery returned to normal.

Visualization of the urinary tract revealed no

evidence of obstruction.

This case of recurrent pyuria, uncomplicated by urinary obstruction, is the type of case in

which we are immediately interested.

An opportunity has presented itself for the study at autopsy of 2 cases similar to the one just described. In both instances death was due to extra-urinary tract lesions. Thus it came about that we were able to study the urinary tracts in two individuals who had suffered from repeated attacks of pyuria and who would be still living had not intercurrent infection carried

In both subjects the kidneys revealed an irregular scarring. We interpreted these scars as being due to previous acute suppurative renal lesions which undoubtedly gave rise to pyuria. The remainder of the urinary tract in both instances

revealed no gross pathologic changes.

Histologic studies revealed similar changes in the kidneys of both subjects. Replacement of parenchymal tissue with scar tissue was observed. In these scarred areas glomeruli were found in varying stages of destruction. A few appeared normal, others revealed slight replacement with connective tissue, others more extensive replacement, and still others were completely replaced with connective tissue.

Kidney tubules in scarred tissues revealed evidences of partial or complete destruction. Some of them were small, distorted, and filled with

foreign material,

In addition to these findings, the scarred portions of the kidney also revealed areas which were infiltrated with lymphoid cells, plasma cells, and large mononucleated cells. This type of cellular reaction is usually interpreted by pathologists as a chronic inflammatory process.

These, then, are the data-the facts in the case. The question is—what can we infer from these data?

In this connection, is it not reasonable to assume that such damaged glomeruli and tubules as have just been described would be more likely to suffer an insult than would normal kidney tissue? In other words, might not normal kidney tissue withstand the onslaught of an infective agent better than such damaged tissue as we have demonstrated? Again what may we infer from the accumulations of lymphoid cells, plasma cells, and large mononucleated cells-reactions which are usually interpreted as evidence of ehronic inflammation by the pathologist. In this eonnection, we can merely speculate, for there is no conclusive proof at present available. Is it not possible to assume that there may be still lurking in such a focus an infective agent which, under suitable circumstances, might light up and give rise to an acute inflammatory process—an acute pyuria. With more assurance could it not be assumed that such a process as the one described might represent a damaged area of kidney which under suitable conditions of lowered resistance might be fanned into a new flame and result in a recurrence of pyuria.

Comment: In conclusion, it would seem that there is sufficient evidence to warrant the attachment of a greater significance to pyuria as it occurs in infancy and probably also in later childhood. For many years it was assumed that inflammation of the pelvis of the kidney was responsible for pyuria in most of the cases diagnosed "acute pyelitis." But this was an unproven assumption. From data now available it is apparent that the pyuria of the type ordinarily so diagnosed is due, in the majority of cases, to suppurative interstitial lesions of the kidney tissue itself. Hence, a new significance is attached to the ease of so-called "acute pyelitis."

The treatment of so-called "acute pyelitis" has

been directed chiefly toward the urine and the urinary tract below the kidney. This fact perhaps accounts for many of the discouraging therapeutic results. With the establishment of the pathology underlying the condition it is possible that more effective therapeutic procedures

may be developed.

Rest and quiet and fluids apparently still remain the most important factors in the treatment of so-called "acute pyelitis." In those subjects who do not respond to treatment after a reasonable length of time, the urinary tract should be investigated for possible obstructions, and if such are found it is often possible for a skilled urologist to relieve the condition.

In those subjects who suffer from recurrences of pyuria, but in which obstruction to the outflow of urine cannot be demonstrated, the evidence suggests that treatment should be prolonged in order to induce complete healing. Prolonged rest and quiet seem to be of special importance here. In this manner the foci of chronic inflammation which persist in the kidney substance may go on to complete healing, thus rendering recurrences less_probable.

PROBLEMS OF LABOR*

By E. EVERETT BUNZEL, M.D., NEW YORK, N. Y.

divided into three phases, each one of which frequently taxes the trained obstetrician to the utmost, for the difficulties and abnormalities which may arise in the ante-partum, intra-partum and post-partum periods are many. However, when a patient places herself in a physician's hands for such care, she thinks primarily of her approaching labor and therefore, during the prenatal period, she cooperates and follows instructions to the best of her ability so that she will be in the finest physical condition when that long anticipated day arrives.

Fortunately for the patient, she is unaware of the problems which may confront her doctor during the hours of her labor, her one concern at this time being to have it over with safely, and as painlessly and as quickly as possible. Obstetrical patients today are delivered in hospitals whenever possible as it adds not only to the safety of the patient but also to the ease and to the peace of mind of the attending physician. Therefore, when labor is definitely established the patient is instructed to go to the hospital where, after being admited, she is prepared and is given an enema. The later is used chiefly for two reasons—in the first place to empty the lower bowel and secondly, because of its heat to stimulate and increase uterine contractions. case is relatively normal, labor will proceed without interruption and our first problem therefore. comes near the end of the first or the beginning of the second stage at which time the patient asks for something to relieve her pain.

OBSTETRICAL ANALGESICS

The choice of analgesic to be employed cannot definitely be determined before the patient is seen in labor. Many women ask their obstetricians for a certain analgesic of which they have heard or about which they have read in some newspaper or magazine article. They assume that because it has been used advantageously with some patients, it will therefore be successful in their own cases. I am fully convinced that the best way to handle this situation is to make no promises and to say that relief and help will be given as soon as possible, but that the choice of analgesic must be determined by the character of the individual labor.

The inhalation of nitrous oxide with each uterine contraction may be instituted moderately early in the first stage—that is when the pains have a frequency of five or six minutes—and it may be continued throughout the rest of the labor. However, for the actual delivery ether is most satisfactory. Nitrous oxide offers the patient great relief and, if given properly, will not interfere with the expulsive forces of the second stage. The administration of gas requires the constant presence of an anæsthetist and does not give relief to the almost ever-present backache which persists between pains. In spite of this, it is a safe anæsthetic for both the mother and the child; it may be given when the membranes are either intact or ruptured, and there is the distinct advantage of being able to discontinue its use if and whenever necessary.

Twilight sleep as originally described has been abandoned in most institutions because of its danger to the child. Too many babies were born asphyxiated and blue, and although many of them responded to various means of resuscitation, nevertheless some failed to react. However, a modification of this method, using small doses of morphine with scopalomine, may be employed in the first stage of labor or when delivery is not anticipated for at least two hours. The type of case best suited for morphine and scopalomine is the one in which the first stage is long and drawn out, and in which the cervix is slow to dilate. In such a case there is usually little advance of the presenting part and the uterine contractions fail to increase in frequency or dura-Such a patient becomes mentally as well as physically exhausted and requires rest. It is not an uncommon observation that after giving this type of patient morphine gr. 1/6 or 1/4, and scopalomine gr. 1/200 or 1/150, she will sleep or rest comfortably for an hour or two and then proceed with a much more active labor. Sometimes a second hypodermic is indicated but it should be kept in mind that the scopalomine may be repeated but not the morphine. Following this, labor may continue normally and for delivery it is quite permissible to use gas and ether.

The Gwathmey method of rectal analgesia in the past few years has been used extensively and in some institutions it has become almost a routine. Its technique of administration is well known to you, but a good many obstetricians have modified the method by eliminating one or

^{*}Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

two of the hypodermic medications or by giving the rectal anasthetic alone However used, the best results are obtained when the treatment is instituted after the labor is well advanced. The interine contractions should have a frequency of three to four minutes, and the cervix should be dilated at least two and one half to three fingers After starting the treatment, many patients will sleep and the labor will continue without inter-Usually only a small amount of mhalation an esthesia is required at the time of deliv-The cluef disadvantages of rectal analgesia (1) the length of time consumed in producing the desired result after the decision has been made to use it, (2) the difficulty sometimes encountered in a patient who is unable to retain the rectal medication, and (3) the occasional baby who is born anæsthetized

More recently, pernocton has been used as an obstetrical hypnotic or analgesic and in our hands at Sloane Hospital it has proven itself a very valuable drug reclinically it is a 10 per cent aqueous solution of the sodium salt of the -econdary buty1 - β - bromally1 barbituric acid and is administered intravenously It has many ad vantages over other types of analgesics because its dosage may be regulated, it may be used in any well advanced first stage or even in the sec and stage of labor, in cases of vertex or breech presentations, whether the membranes are rup fured or intact, it does not increase the incidence of forceps delivery, nor does it increase bleeding We have noted no increase in post partum asphyxia of the newborn nor any ill effects on the mother. It is best given when the cervix is three or more fingers dilated and when the interval between uterine contractions is four nunutes The average initial dose of pernocton 18 44 to 5 cc, the dose increasing up to 6 ce in proportion to the weight of the patient is most important to inject this drug slowly into the vein, at the rate of not more than 1 e.e. per As a rule the patient is asleep before the injection is completed. It is my belief that not only labor continues normally but that labor Soon after giving the is actually shortened medication there is a slight fall in the patient's blood pressure but not to such an extent as to cause any alarm Patients to whom pernocton has been given should not be left imattended as they may be slightly aroused by and restless with each uterine contraction. With two of my own cases there was such a degree of excitement that the patients attempted to get out of bed and had But even in these to be forcefully restrained cases the results were none the less excellent, for neither of the patients remembered anything about their labors. Should the effect of the drug begin to wear off before the end of labor, a seeond smaller dose may be used intravenously or Not infrequently it has been intramiiscularly our experience to find the imminimed sac of

membranes or the caput itself presenting at the vulva with the patient uncomplaining or asleep for pernocton does not interfere with the involutary expulsive forces of the second stage. For delivery, nitrous oxide or ether may be used after pernocton with perfect safety to the mother and child

With introus oxide, morphine and scopalo nime, rectal ancesthesia, and pernocton the obstetrician of today has many methods to alleviate and relieve the pains of labor. Other methods, such as spinial amesthesia have been reported to afford good results also

FORCEPS

The use of obstetrical forceps has become so wide-spread that only the so called "plunging multip' or the rapidly advancing primigravida In the hands of the are delivered normally skilled obstetrician this may be justifiable, but in a teaching institution it is a good policy to in struct the students not to interfere with the normal mechanism of labor unless there is a definite indication Therefore, in principle, we should not turn to operative obstetrics unless there is evidence of insufficient expulsive forces or unless the safety of either the mother or the child is compromised Careful observation of the patient's condition as manifested by her pulse rate and blood pressure will serve to indicate any necessity for hastening the delivery Likewise frequent auscultation of the fetal heart will deteet any marked change in its rate or rhythm, both of which usually occur when an umbilical cord complication exists or as an evidence of any other cause for fetal distress. With these indications, a forceps delivery should be done if it may be accomplished by either a low or medium forceps operation Should a prolapsed pulsating cord be found on examination, and if it may not be replaced easily, an internal podalic version with subsequent breech extraction is the method of This is true also in cases in which the vertex is floating or only loosely engaged in the pelvic brim Most obstetricians today are in accord that a high forceps delivery is one of the most difficult obstetrical operations and should be avoided if possible Cases such as these which require immediate delivery and in which there is no contra-indication should be delivered by version and breech extraction

On the other hand, having decided that a for ceps operation is indicated the obstetrician's next problem is the selection of instrument to be used. For the usual low forceps operation, the choice is between an instrument with a solid blade such as the Tucker McLane type or of a fenestrated blade, such as the Simpson. The selection of type of forceps to be used is largely a matter of individual preference and training, not only for a low forceps but for any forceps delivery, and I am certain that there is still a place in obstet.

rics for the solid blade instrument in cases where the vertex is low and in which rotation of the vertex is unnecessary. I believe this, not only because of the much greater ease of application and removal of the blades, but also because they are less likely to produce vaginal and perineal lacerations and, if properly applied to the vertex, they are no more apt to do trauma to the baby. If, however, there is dystocia due to the bony pelvis, if rotation is necessary, or if the solid blades should slip, then a fenestrated instrument The more difficult types of delivis indicated. ery with the vertex high in mid pelvis are facilitated by the use of the Haig-Ferguson forceps with traction rods, or the Barton forceps with its hinged anterior blade, especially when the vertex is in transverse position. There are many other types of instruments described and used, but every obstetrician must select the type he prefers in each individual case.

Associated with forceps deliveries is the use of episiotomy. As I decry the routine use of forceps as advocated by some in all deliveries, so do I deplore the routine use of incising the perineal tissues. There are some cases which can be delivered without any laceration and a great many more in which only a small tear of the fourchette may occur. It is argued by some that without episiotomy a resultant gaping vulva, a relaxed floor, or a mild to moderate degree of cystocele and rectocele will exist. In my opinion episiotomy should be done only on such cases in which lacerations appear inevitable, in which haste is an important factor, and in cases of breech extraction when difficulty is anticipated with the extraction of the after-coming head. I am opposed to routine episiotomy for it is not always necessary, because many times the episiotomy wound is deeper and more extensive than a natural tear would be, and because of the possibility of infection and therefore faulty healing in a case which might have been delivered without laceration.

TRIAL LABOR

During the ante-partum period, the obstetrician has ample opportunity to familiarize himself with the character of the pelvis of each patient so that at full term he has decided in most instances on a definite course to follow. Nevertheless, there are some cases in which even the most experienced cannot determine whether a pelvis slightly contracted will make delivery per vaginam impos-It is the pelvis slightly contracted at the inlet which confronts us with this problem, because even with the most accurate mensuration possible, with x-ray of the pelvis, and estimation of the size of the fœtal head, we are unable to prognosticate the ultimate result of labor. Consultation in such instances is always advisable but even then it may be necessary to resort to trial labor.

There is no definite time limit to a trial labor nor can we accurately define it, for many factors are involved, the most important being the character of the labor pains as estimated by their frequency, duration and intensity. Three or four hours of weak, irregular contractions cannot be considered a trial labor, for moulding of the vertex, and softening and retraction of the cervix occur only after real hard, firm and frequent contractions have persisted over a period of several hours. During this time no vaginal examinations should be made because abdominal palpation should reveal all the preliminary information required. We may use analgesics during the trial labor if we find the patient fatigued, but we must keep in mind that a trial labor to be convincing must be sufficiently long and the contractions forceful enough to cause descent of the vertex through the pelvic brim. If this takes place, vaginal delivery is indicated, assisted when necesary by forceps or if the pelvis is of the male type, by doing a version and breech extraction should the cervix offer no obstruction. But when moulding and descent of the vertex through the inlet do not occur, and the cervix has not become dilated and retracted, then Cæsarean section should be done.

Sometimes in a case considered to warrant a trial labor, the membranes may rupture at term prior to the onset of labor pains or very soon after. If the head is still floating or only loosely engaged, a vaginal examination should be doneoften under an anæsthetic-with complete vulval and vaginal preparation, to determine not only the consistency, length and dilatation of the cervix, but also to make an attempt with pressure from above to fit the vertex into the brim, to correct a parietal presentation should it exist, and at the same time to further flex the head if nec-It is well recognized that such a case with membranes ruptured is less likely to deliver vaginally and therefore it is important to make this examination early so that if Cæsarean is chosen as the method of delivery, it may be done without further delay.

The choice of method of performing an abdominal Cæsarean section is often quite a problem in itself. The low, mid-line abdominal and uterine incision is usually preferred in the purely elective case, but if a trial labor has been given and the membranes are ruptured, and if several vaginal examinations have been made, then a low flap or extra-peritoneal operation should be done, resorting to a Latzko, with its greater difficulty and attendant traumatic accidents, only if the case is febrile, or after instrumental attempts from below have failed. The low flap or transverse cervical Cæsarean operation may be done with only a relatively small amount of cervical dilatation, but the Latzko operation should not be attempted until the cervix is dilated considerably further.

Dystocia

When labor does not progress normally, we must ascertain the cause. This may be found in either the fetus or the patient. The size of the fetus, its presentation, or its position may interfere with the advance of labor. On the other hand, the maternal hony pelvis, uterine inertia, or failure of the soft parts to dilate often pro-Occasionally combinations of duce dystocia. these factors exist, and the importance of recognition of the factors involved must be emphasized. Too much stress cannot be laid on diagnosis in these cases, because the line of procedure to be followed depends entirely on the actual cause of the dystocia in each instance. In few other problems of labor does practical experience count for so much. The sizing up of the case at hand cannot be learned out of but only from similar clinical experience.

Face presentations, though rare are occasionally encountered, but the trained accouchere must be able to deal with this type of case as with any of the other less rare abnormal presentations. The face presentation with chin anterior seldom produces great difficulty unless there is considerable disproportion between the passage and passenger and, if labor is allowed to continue, the mechanism will be practically normal. But if the chin rotates posteriorly, dystocia is almost inevitable. When this condition is diagnosed some type of conversion is essential. In practically all instances an attempt should be made to convert the face into a true vertex by displacing the presenting part above the brim of the pelvis, and then with the operator's hand through the cervix, to flex the head. If this is accomplished the labor will continue normally. Failing in this attempt, one may do podalie version.

With occipito-posterior positions, we again meet with the possibility of dystocia. Here, too, as with the face presentation, a great deal may be done prior to the onset of labor if the diagnosis has been made. However, if not recognized until the patient is seen in active labor, the size of the fetus and pelvis, as well as the actual advance made during labor must be considered in judging the proper procedure to follow. Not infrequently an unrecognized persistent occiput posterior will deliver as such, or when low in the pelvis may be manually rotated. But if high in the pelvis and labor does not advance the vertex, then it becomes necessary to interfere. Forceps, such as those devised by Barton, may be used to produce both descent and later rotation of the vertex or, as with face presentations with chin posterior, we may displace the vertex out of the pelvis and then guide the occiput anteriorly, or once again we may do an internal podalic version.

Uterine inertia not infrequently occurs in cases in which the presentation and position, as

well as the size of the fetus and pelvis, are normal. But more often inertia is encountered in the short, thick-set type of individual whose pelvis is somewhat of the male type and in whom there is usually some evidence of endocrine dyserasia. Change in the position of the patient on the delivery table in order to improve the inclination of the pelvis together with small doses of pitnitrin may radically help to overcome the result of uterine inertia and then forceps delivery may be effected. On the other hand, associated with uterine inertia we may find a cervix which fails to dilate completely. The problem of treating this type of cervix is a perplexing one. If the eervix is well retracted, fairly well dilated and thin, we may manually produce dilatation; or if the cervix is soft, moderately thick and edematous, but almost completely dilated we may introduce the forceps blades within the cervix and then with gentle steady traction we may be able to work the cervix over the vertex. However, there are certain cervices which fail to dilate satisfactorily and which are best treated by incision. This type of cervix is the one in which both dilation and retraction are incomplete and which remains firm and unyielding. A single anterior incision is often all that is necessary to permit advance of the vertex and delivery, but many obstetricians will hesitate to do this because of inexperience, as well as because of the more troublesome repair when the labor is finished. A caution should be interjected here because to ineise the cervix it is essential to have both proper exposure and adequate assistance.

Hemorrhage

As a complication of labor, there is no condition which causes the obstetrician more worry than hemorrhage. Even with the most careful prenatal supervision, bleeding may arise in any case in the ante- or intra-partum periods. Hemorrhage may result from premature separation of the placenta, be it either due to placenta prævia or accidental hemorrhage; it may result from lacerations of the cervix, or from relaxation of the uterus immediately post-partum.

The hemorrhage occurring in cases of placenta prævia is more often sudden in onset and profuse, but it has been stated that the first hemorrhage is never fatal. This permits the patient time to report her condition, and time to get to a hospital. The hemorrhage however, resulting from the separation of a normally implanted placenta—i.e., accidental hemorrhage—is less acute and sometimes is even concealed. The problems to be solved in these types of cases are to determine the cause of the bleeding, the extent of the hemorrhage as estimated by the patient's general condition and blood count, and to decide upon the method of treatment. At the Sloane Hospital we have a rule which prohibits a vaginal examination being made on a case with a history of hleed-

ing until the patient is prepared and the operating room is set up for the use of bags. This has been found expedient because if the case is one of placenta prævia, a brisk hemorrhage may follow the examination, due to further separation of the placenta by the examining fingers.

The method of treatment in both types of cases is more or less entirely dependent upon the condition of the cervix and the presence or absence of the fetal heart. More and more Cæsareans are being done in the interest of both the mother and the child. This is especially true if we are dealing with a placenta prævia centralis or in any case in which the cervix is long, rigid and only slightly dilated. If, on the other hand, the cervix is soft and somewhat dilated, and if the patient's and baby's condition will permit several hours of labor, we will choose the vaginal route and the use of the elastic hydrostatic bag. In such instances, a bag will induce labor, dilate the cervix and, in cases of placenta prævia, will also control the bleeding. During this period, transfusion is frequently used and then, when the bag has come through the cervix, delivery may be hastened if necessary by rupturing the membranes, applying forceps, or by performing an internal podalic version followed by breech extraction.

One cannot pass by the question of Cæsarean section for cases of accidental hemorrhage without referring to the occasional case in which the operation should be completed by supravaginal hysterectomy. This becomes necessary when the uterus on opening the abdomen, is seen to be extensively discolored in several large areas as a result of hemorrhage and thrombosis in the uterine musculature. Such a uterus if not removed does not contract well, and bleeding may continue after the operation, and in addition will greatly increase the morbidity during the post-operative period.

Post-partum hemorrhage which occurs immediately after delivery of the baby may be produced by relaxation of the uterus or by cervical lacerations which may extend and involve the lower uterine segment. If a uterus at this time is firmly contracted, and bleeding is profuse and continuous, vaginal examination should be made to ascertain the exact source of the bleeding.

This should be done digitally first, because of the possibility of lateral vaginal tears which can be felt better than seen, and secondly, the cervix should be exposed and carefully inspected. If the bleeding is from a badly lacerated cervix, I prefer manually to remove the placenta from the uterus and then to pack the uterus down to the cervix. Then by grasping both the anterior and the posterior lips of the cervix with sponge sticks, the bilateral lacerations may be exposed. This exposure may be greatly facilitated by an assistant or nurse making downward pressure on the fundus. Through and through interrupted catgut sutures placed in the lacerated edges of the cervix will control the bleeding at once and then the uterine packing may be continued into the vagina, especially into the lateral fornices. Once again I must emphasize the absolute necessity for obtaining the best possible exposure.

In cases of post-partum bleeding without cervical lacerations, due to placenta prævia, or to such causes as over-distention of the uterus produced by multiple pregnancy or hydramnios, or due to atony of the uterus from a prolonged labor or an excessive amount of anæsthetic having been used, I am convinced that if the uterus does not respond quickly to pituitrin, the placenta should be manually removed and a thorough tamponade of the uterus and vagina should be done. I believe in doing this promptly because less blood will be lost and therefore, in spite of an additional intra-uterine manipulation, there will be less shock to the patient. The tamponade may be done under nitrous oxide or ether.

In cases of marked hemorrhage we may use an immediate 5% or 10% glucose infusion, but a transfusion should be given just so soon as a donor may be obtained, using 700 to 1000 c.c., depending upon the estimated blood loss. This large transfusion serves two purposes: in the first place it may save the life of the patient at that time, and secondly, it gives the patient a great boost at the beginning of her puerperium.

With the onset of the puerperium the problems of labor are over, but the patient's convalescence during the post-partum period and her ultimate recovery are entirely dependent upon both the management of the prenatal period and the manner in which the labor has been conducted.

ATRESIA OF THE VAGINA

By ARTHUR M. DICKINSON, M.D., ALBANY, N. Y.

ATRESIA of the vagina is met with so seldom by the average physician that it deserves some comment. Vaginal atresia may be either congenital or acquired. In the congenital type there is most commonly an imperforate hymen or a hymen with only a small opening in it. Occasionally transverse septa of the vagina do occur. The acquired type of atresia may follow severe vulvovaginal infection; it may result from the injuries of childbirth or follow repair of these. The congenital type of atresia is usually discovered in the carly days of adolescence but occasionally patients with this type go on to adult years and marriage without discovery.

Sometimes there is seen in the new born female an imperforate hymen, bulging outward due to a collection of secretions within the vagina. This secretory activity probably results from stimulation derived from the placenta. Treatment of this condition consists of incision and drainage.

However, the presence of an imperforate hymen is rarely noted until some time after the onset of puberty. Before this time, examination of the vulva is not made unless there is some occasion for it. After puberty this is also too often true, especially in those girls who do not menstruate. These young girls with an imperforate hymen come up to puberty; they have the usual secondary changes which occur at this period, such as enlargement of the breasts, growth of pubie hair, etc.; periodically they have the subjective symptoms usually associated with menstruation but apparently do not menstruate. If the only anomaly is the imperforate hymen and the internal organs of generation are normal, this is what occurs. With each menstrual period the blood accumulates in the vagina behind the imperforate hymen. At each period the accumulation is increased until the vagina becomes quite distended, which condition is spoken of as hematocolpos. More blood accumulates and the uterns becomes markedly dilated by increasing amounts, which condition we call hematometra. Next the increasing pressure causes the Fallopian tubes to be dilated and filled with blood and finally blood may be extruded into the peritoneal cavity as occurred in a case recently seen. This termination is unusual, however, for commonly the ends of the tubes seal off preventing the escape of blood into the peritoneal cavity. At any stage of this process, infection may take place in the retained blood, and so abscess formation may result in the vagina or in the distended uterus or tubes the latter occurs, a clinical picture not unlike pelvic inflammatory disease is seen If the hematoma remains uninfected, an abdominal tumor may be the first real symptom causing the patient to complain. In other instances pressure on

the urinary tract by the dilating vagina may produce symptoms suggesting some disease of the urethra or bladder. Recently there was reported such a ease in which urinary retention in a young girl was caused by a hematocolpos.

I would like to cite two cases which illustrate some of the points mentioned above. The first case is that of a girl, age 15, who entered hospital with a diagnosis of an acute pelvic inflammatory disease on a venereal basis. She was badly dehydrated due to vomiting of several days' duration and appeared quite ill. Her temperature was 103 degrees and pulse 140. The lower half of the abdomen was rigid and painful and somewhat dis tended. There was some purulent discharge from the vulva. Under the usual conservative treatment for acute pelvie inflamntatory disease, the condition of the patient improved rapidly. Then a more eareful examination was made of the patient. The only finding of importance was that of a thick hymen, intact except for a small opening and a suspicion of a semifluctuating mass in the vagina noted by rectal examination. Subsequently the hymen was incised, releasing a large amount of foul pus and broken down blood, After this procedure, the improvement of the patient was rapid. Previous to discharge from the hospital, a careful bimanual examination was made under gas; this disclosed no other anomalies of the genital tract and gave assurance that the vaginal opening was not being constricted by scar formation. The second case was another girl of 15 years. She was admitted to the hospital complaining of a moderately painful pelvic tumor. She had never menstruated. Six months before, slie had been operated upon through the abdonien for a similar tumor. The physician who operated was called and he stated that at operation he had found a large uterus, greatly swollen tubes and some free blood in the pelvis. One tube and ovary were removed. Recovery was apparently uneventful. At the time I examined the patient the secondary sex characteristics were quite evident. The breasts were large and of the puberty type; hair was noted on the pubes. There was a smooth, hard globular tumor in the pelvis, the size of a grapefruit. It seemed quite fixed. Recto-abdominal examination revealed little except to confirm the above. Attention was then focussed upon the vulva and the liymen was found to be blue and bulging and apparently imperforate. With excision of the hymen and escape of the retained menstrual blood, the abdominal tumor disappeared. Subsequent observation of the patient through the next few months showed normal menstruation and no contracture of the vaginal orifice. These two cases illustrate the value of definite details of the menstrual history in . young girls and the need for careful examination of the external genitals, if the patient appears to have the secondary sex changes but has not menstruated.

Among embryologists there is still marked disagreement as to the etiology of the imperforate hymen. One group of investigators insist that an imperforate hymen is due to a failure of absorption of a normal diaphragm; the other group is equally positive that an imperforate hymen is the result of the growth of an abnormal diaphragm. As this point is of academic interest and of little practical value, we will cite no arguments for either group.

Imperforate hymen in the adolescent is treated by partial or complete excision under aseptic precautions. Simple crucial incision rarely suffices for the edges have a noteworthy tendency to re-unite thereby defeating the purpose of the operation. Excision of the membrane with suture of the raw edges is the safest procedure. In the presence of hematocolpos or hematometra one must be careful to avoid infection which may result seriously. After operation the vagina may be drained with a soft rubber tube well wrapped with vaseline gauze.

In the adult, imperforate hymen is not so com-If the internal organs of generation are normal, the regular menstrual discharges accumulating in the vagina will have caused symptoms resulting in proper treatment before maturity is reached. On the other hand if the menstrual function is not established due to rudimentary or absent internal genitalia, persons may go on to adult life without the discovery being made. In some instances marriage has taken place and the hymen being sufficiently elastic, no complaint is Recently I had the privilege of seeing such a patient operated upon. She entered hospital complaining of a pelvic tumor with slight pain. She was forty-two years old and had been married for ten years. She was very obese and showed some of the male sex characteristics. She had never menstruated. The pelvic tumor was the size of a grapefruit; it was moderately firm and seemed fixed in the pelvis almost in the mid line. On attempting to do a vaginal examination, what appeared to be an imperforate hymen was found. Rectal examination gave no additional information. A crucial incision of the hymen was made at operation, but behind the membrane no existing vagina could be found after a long and careful search. Abdominal exploration revealed a tense ovarian cyst and a very small infantile uterus located high in the pelvis. As stated before, this finding is commonly associated with congenital absence of the vagina. It is a development defect for which no cause can be assigned. Treatment of the imperforate hymen

in the adult, or what appears to be this, should healed and the final result was satisfactory.

be entered upon with a guarded prognosis. One should not be too rash in his promises about results. Before any operative procedure is commenced, there should be a very painstaking pelvic examination by combined abdominal and rectal routes. If it is found that the internal genitals are very small, there may well be no vagina behind what appears to be an imperforate hymen. This being the case, one must be prepared to construct a vagina if the patient insists. If the internal organs appear normal, then we are much more likely to find a vagina of sorts behind the hymen.

The acquired type of vaginal atresia in adults commonly results from childbirth or from surgical repair of these. Occasionally atresia is seen as the result of prolonged infection such as syphilis, tuberculosis or as the result of malignant or premalignant changes. It does seem that the occurrence of complete vaginal atresia after childbirth is to a large extent preventable by careful repairs. I would like to cite two cases which illustrate the acquired type of atresia, the first following childbirth and the second following a perineal repair. The first, Mrs. W., aged 24, came to my office complaining of inability to have intercourse. This dated from the time of a forceps delivery, followed by an immediate repair of a torn perineum, some 15 months before. Since then she had menstruated regularly, but somewhat scantily. Examination showed what appeared to be a hymen with only a pin point perforation. At operation, however, it was found that what appeared to be hymen, really consisted of the two lateral vaginal walls which had apparently been sutured together to a depth of about one inch. These were separated by blunt and sharp dissection and a plastic operation was done to cover all raw surfaces. This resulted in the restoration of a satisfactory vagina.

The other case was that of a widow, age 42, who complained of an abdominal tumor which her physician considered to be a myoma of the uterus. Five years previously, she had had an operation for prolapse of the uterus, the nature of which she did not know. She did recall that she had had an abdominal and vaginal operation however. Since the operation she had not menstruated. Careful examination disclosed that the vaginal repair had been done so well, that the anterior part of the vaginal cavity had been completely obliterated. Combined rectal and abdominal examination showed that the tumor was apparently uterine in origin. At operation the vaginal walls were separated by dissection and a great amount of old blood was released from the vagina and uterus. This caused the uterine tumor to disappear. The vaginal walls were kept apart with vaseline gauze until the raw surfaces were

Annual Meeting, April 3-5, in the Waldorf-Astoria. New York City.

ASPECTS OF THE ANNUAL MEETING

The Annual Meeting of the Medical Society of the State of New York will exemplify at least five aspects of the practice of medicine:

- 1. As a science;
- 2. As an art;

- 3. As a business;
- 4. As a social service;
- 5. As a philosophy,

Modern medicine is a science developed by research into the nature of the living actions of the body and mind. The doctor who has an outstanding knowledge in any corner of medicine is a specialist who is admired by his fellows. There will be abundant opportunity to see and hear and talk with the hundred or more specialists who will appear on the scientific program, and will explain the diseases and abnormal conditions of man as an impersonal organism.

But to most physicians the practice of medicine is an art as it was during the ages when men and women comforted and nursed one another long before science was born in the human brain. The first concern of the family doctor is for the safety and comfort of the sick person rather than the exact nature and extent of the disease which afflicts the patient. The art of dealing with patients in distinction of diseases will be told in the lectures before the scientific sessions of the Annual Meeting; but the art will also be exemplified during the whole morning and afternoon of Clinic Day,—the first day of the Annual Meeting,—in thirty of the leading hospitals in New York City.

The practice of medicine is also a business, for the doctor must support himself and family while he brings relief to others. He also must be a salesman who inspires officeholders and voters to supply the service which the community owes to the sick. The physician is also a business promoter and demonstrator, and a manager in all matters leading to hospitals, health departments, and welfare workers. All these and other economic problems and activities will be discussed in the House of Delegates.

To heal the sick is a social service which has been recognized through all ages. Its more modern ideal is to bring the benefits of all forms of scientific medicine within the reach of every person. The extent and ramifications of this field of work have been surveyed and evaluated by endowed committees operating throughout the nation; and their findings constitute a challenge to physicians to devise the means of supplying the medical needs of those unable or unwilling to provide the service for themselves. The problems of social service will receive special attention in the House of Delegates and in the general sessions of the meeting.

Every physician has a philosophy regarding the practice of medicine, which he is ready to express under certain conditions, especially to his confreres whom he meets informally and casually. The scientific investigator who wishes to ascertain the philosophy or creed of the medical profession in any subject may obtain the necessary data from friendly conversations with doctors in their moments of leisure in the lounging rooms.

The standard of the modern practice of medicine requires that a physician shall be not only a family doctor, but also a scientific investigator, a business man, a sociologist, and a philosopher. Knowledge and experience along all these five lines of thought and action may be gained pleasantly and efficiently at the Annual Meeting.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Influenza Epidemic: This Journal of April, 1908, contains a report of a symposium on Grip held by the Medical Society of the County of New York, on January 31, 1908, in which Dr. J. A. Lichty described an epidemic of grip in Pittsburgh, as follows:

"The epidemic of influenza which prevailed in the city of Pittsburgh, Pennsylvania, began at the end of the second week of December, and slowly subsided during January and February of this year. The epidemic was as widespread, though probably not quite so severe, as in the noted pandemic of 1889 and 1890. Whole families, including servants and all associated with the household, were afflicted in rapid succession. The onset was sudden and severe, the usual symptoms of 'pain all over' being most The temperature did not go unpronounced. usually high, nor did it seem to be in accord with the severity of the symptoms when the patient took to his bed.

"In typical cases, where proper treatment was established promptly, the attack was unusually short, lasting from two to three or four days. When treatment was neglected the symptoms dragged through one or two weeks. With proper care very few cases had any complications, and most of them were up in a few days with the usual languor and stiffness. Peculiar to this epidemic seemed to be the general complaint of sore throat. Another peculiarity which seemed to mark this epidemic was the frequency of involvement of that portion of the nasal cavity which is immediately betwen the eyes. The pain here was usually intense, and it seemed that many of the complications were due to the inflammation of this portion of the nasal mucous

"For a time, and early in the epidemic those physicians who were frequently exposed to the disease fell victims. Every evidence was present to show that the disease is highly contagious."

MEDICAL PROGRESS

Functional Bundle-Branch Block (Partial) Paradoxically Relieved by Vagal Stimulation. -Louis H. Sigler says that to explain bundlebranch block, not due to anatomic changes in one of the bundle branches, one must assume the presence of certain functional disturbances interfering with the free passage of the impulse along one of the branches. The possible factors that may cause such disturbances without leaving any permanent damage discoverable on postmortem examination are bundle-branch fatigue, toxic states, local interference with the blood supply, and nervous inhibition. Although toxic states and local interference with the blood supply as causes of bundle-branch block have not been fully established, fatigue of the conducting apparatus in the ventricles and vagal inhibition causing such block are fairly well proved. Sigler cites instances which prove conclusively that bundlebranch block may occur as a result of excessive vagal activity. It would therefore appear irrational and paradoxical to expect the removal of such block by vagal stimulation. In a case which is here reported in detail left vagal stimulation apparently removed rather than caused such block. The patient, 41 years of age, complained of sharp attacks of pain, which appeared spontaneously about every three days and lasted only two or three seconds. A moderate sinus bradycardia and slight arrhythmia suggested the possibility that vagal influence was the underlying cause of the interventricular conduction disturbance. The electrocardiogram in this case corresponded to the so-called "arborization block" of Oppenheimer and Rothschild. The Q-R-S complexes were prolonged beyond 0.1 second, notehed, of low voltage, and there was absence of the typical character of the T wave found in complete bundlebranch block. The normal complexes were easily restored by left vagal stimulation, which proved that the condition was not dependent in this case upon any anatomical pathology. After discussing various theories as to what caused this conduction disturbance, and how vagal stimulation relieved it, Sigler concludes that it was not the direct vagal effect on the bundle branches which produced the results in this case. It was merely the slowing of the impulse formation in the sinoauricular node, under left vagal stimulation, giving increased rest to the conduction apparatus of the ventricles, and it was this increased rest which restored normal conduction. Abnormal Q-R-S complexes occurred after as long a rest as 0.56 of a second, and normal complexes were restored by additional rest of 0.08 of a second.—American Journal of the Medical Sciences, February, 1933.

Physiochemistry of the Blood in Lobar Pneumonia .-- On the basis of a study of the literature and of 11 personal cases of lobar pneumonia, M. Sigon concludes that at the peak of the attack the blood presents a tendency to a more or less compensated alkalosis, from hyperventilation, with a lowering of the alkaline rescrve. urinc, on the other hand, shows an orientation toward acidosis, in that the elimination of organic acids and the hydrogen ion concentration are increased during the disease, to descend again after the crisis. The water and salt exchange is characterized by two phenomena: retention of water and chlorides, in both tissues and blood, during the attack, followed by a urinary crisis with discharge of chlorides during convalescence. This chloride retention is not of a renal nature, but is attributable solely to the fact that the amount of these substances in the blood does not reach the threshold of elimination. A lowering of the total protein content as compared with the volume of the plasma was always noted in Sigon's personal cases; the imbibition of the colloids of the serum. on the other hand, was clearly increased toward the crisis and just after it, to decrease again during convalescence. The reduction of proteins scems to have been more apparent than real; their absolute content is probably not diminished by the disease; they are merely more diluted, possess a greater affinity for the water, are more turgid and yield up this water only after the crisis, when with increased elimination of urine the amount of chlorides in the serum is increased, and the plasma mass decreased. It is interesting to note that these variations of colloid equilibrium appear to be less prompt in following the typical critical course of pneumonia and in returning to normal than are the electrolytic variations of the plasma and the acid-base equilibrium of the blood-a fact that is natural enough when one thinks of the immediate influence exerted upon the respiratory exchanges by the state of pulmonary phlogosis and by the high fever. An indirect proof of this was given by the fact that for several days after the crisis the velocity of sedimentation of crythrocytes continued to be markedly elevated. In addition a lowering of surface tension of the blood serum was observed, and a diminution of the difference between dynamic and static surface tension.-Riforma Medica, January 14, 1933.

Pneumococcus Research and Specific Pneumonia Therapy.—Among the exciters of pneumonia, according to Paul Martini, the pneumococcus Fraenkel holds first place. This microorganism has 32 different types, among which

Types 1, 2, and 3 are more constant and more virulent than Types 4 to 32. These 3 are found almost exclusively in pneumonia; the others are commonly met with in healthy individuals as well. An attack of pneumonia is the result either of infection with a virulent type or of decreased resistance on the part of the body. In the latter case, types that are but little virulent may also produce pneumonia. Variations in the virulence of a given type are not observed in any great degree. Studies in the epidemiology of pneumonia are still unsatisfactory; it is not yet known why one individual falls victim to pneumonia and another not. It is probable that constitutional characteristics play a rôle here, as well as factors of immunity and allergy. Immune substances that are type-specific are formed in pneumonia. These drive the cocci out of the blood; the same may be accomplished by injection of type-specific serum. Such serum hastens the crisis and prevents extension of the pulmonary process, but is powerless to promote its regression. For this reason early administration is a prerequisite for its favorable action. The high cost of serum therapy is the chief reason why its use has not been adopted to any great extent in Germany. The introduction of polyvalent serums has not produced much in the way of results. Quinine and optochin give the best promise if administered during the first 3 days. The dangers to the optic nerve reported from the use of optochin are not especially great if optochin base is employed. The simultaneous administration of milk according to Mendel's procedure to prevent too rapid absorption may be responsible for this improvement. It has not been shown, however, that optochin offers any advantages over solvochin (quinine-urethane of Cahn-Bronner). No dependable comparison between the various so-called specific treatments (immune serum, quinine, optochin) has yet been possible. During the War the exorbitant price of serum treatment and the recollection of the injurious action exerted by optochin made solvochin the treatment of choice in Germany.-Münchener medizinische Wochenschrift, January 20, 1933.

Report of a Case of Retotheliosarcoma (Reticulosarcoma) of the Cerebral Hemisphere.—Nathan Chandler Foot and Sander Cohen, writing in the American Journal of Pathology, January, 1933, ix, 1, describe a brain tumor of almost unique character. No description of an exactly similar neoplasm was found in modern text-books on brain tumors. The specimen was removed from a girl 9 years of age, who had been well until eight months before the operation. The symptoms were those exclusively referable to intracranial pressure. The child died two months after the operation, and permission for a general post-mortem examination could not be obtained, but there was no evidence of a primary tumor

elsewhere in the body. The specimen consisted of a mass 7.5 by 6.5 by 6 c.m. in size, fairly well circumscribed and enclosed in a sort of capsule Sections of the growth examined microscopically were found to be composed of nests of enormous and very bizarre giant cells and syncytia, lying in a stroma of rather edematous connective tissue. The cells had a most pleomorphic appearance, ranging through the gamut of morphological va-They contained a varying number of Some cells were strewn with minute vesicular nuclei. Mitotic figures were very abundant and ranged from quasinormal karyokinetic forms to the most bizarre and abnormal, multiple, asymmetrical, cross- or y-shaped types. In certain areas of the tumor there were cells resembling the reticuloendothelium of the lymphoid or myeloid tissues. The authors believe that they have ruled out nervous or neuroglial origin of the tumor by means of specific methods of impregnation and staining. The healthier areas of the tumor indicated a retothelial origin, but against this was the marked lack of vessels and the site of the growth, the retothelial type being notably limited to the base, medulla, cerebellum, and spinal cord. This tumor differed from the cerebral retrotheliomas hitherto described in its very active growth and definitely sarcomatous nature. Authorities agree that these neoplasms originate in perivascular congeries of retothelial cells, and the fact that they may be relatively poorly supplied with vessels is also recognized. It would appear therefore that this growth represents a malignant metamorphosis of such a tumor. The authors state that they have adopted the term "retothelial" for reticuloendothelial, as suggested by Rouley, for the reason that it is not only shorter but more correct.

Catechin (Inhibiting Substance) of the Thyroid Gland and Its Therapeutic Use in Basedow's Disease.-A report is made by Ernst Herzfeld and Alexander Frieder in the Deutsche medizinische Wochenschrift of January 20, 1933, on a series of tests in 18 cases, observed for 8 months, in which a preparation of catechin was used-a substance recently identified by Blum in the circulating blood, with antithyroid properties. One unit of this preparation represents the amount that will neutralize 1 γ (1/1000 mg.) iodine in the form of iodo-thyroid-protein in the rabbit metabolism. One tablet of the preparation contains 10 units of catechin. This is the first standardized restraining substance exerting an influence against the thyroid gland, and the authors have had excellent results with its use. Cases as severe as possible were chosen as a test of its usefulness, in some instances so grave as to contraindicate operation. Most of these cases had been treated for a long time, some by the authors themselves, some by others. It is very important that the right dosage be given, and at first the authors

ise a large enough amount. They began olets a day, but results as a rule did not itil 60 units per day had been given as a . In some cases it was necessary to a daily dosage of 90 units, and then decrease this. In no case was it ever to go higher than this amount. Imit was never observed within the first it appeared as a rule in the second. In cases was the treatment a failure: in one tumor was probably present in addition low's disease, and led to secondary in the other, a girl failed to follow direcen. In all cases a gain of weight was visne exceptional case this gain reached 13.5 months. The pulse rate decreased and I metabolism was considerably lower, es almost normal. Vegetative symptoms a, sudor, etc.) very quickly disappeared. ct on the existing exophthalmus was also od, but the size of the goiter itself was le affected. The length of the treatment turally depend on the severity of the case, age in this series being 4 to 6 weeks, after itermittent treatment with smaller doses

ethod of Closing the Eustachian Tube cal Operations on the Middle Ear. illing attention to the importance of closeustachian tube in radical operations on dle ear, and reviewing the methods-none isfactory-that have been employed, Gun-Imgren recommends the following proce-Vith good lighting, preferably an enlarging makes an incision in front of the labyrinindows through the mucoperiosteum of spanic eavity and with a small raspatory s it from the bone, from the back forward. reoperiosteum of the tube is then curetted n the lateral half of the circumference and p of mucoperiosteum inserted in the tube a manner that the promontorial periosadjacent to the exposed, lateral bony end tube, at the same time forming a wall the tympanic cavity. The insertion can be vithout difficulty with an instrument reig in shape the Yankauer tubal curette the flap is thus inserted in the tube, any membrane left around the tubal orifice is d as thoroughly as possible, after which iersch method is used to cover the exposed f the promoutory and the exposed surface flap, which is easily done by the method of pidan. This consists in spreading a thin of lanolin or other neutral fat on a piece linen cloth, and placing the Thiersch flap with the epidermis facing the fat. After er of cloth with the flap has been propted and placed, the tympanic cavity and the tost part of the auditory meatus are tam-

poned with a small strip of gauze, the remainder of the cavity being tamponed with a perforated rubber finger stall filled with gauze. The finger stall is removed after twenty-four hours, and the tamponade in the tynipanic cavity after about five days, the strip of linen usually accompanying it, as the Thiersch graft will probably have grown fast by this time.—Acta Medica Scandinavica, December 14, 1932.

Four Cases of Ocular Affections, Presumably Tuberculous, Favorably Influenced by Gold Therapy.-The favorable results that have been published with respect to the use of gold therapy in pulmonary tuberculosis have led Felix Terrien to report four unusual cases following ocular infections which he has treated by this method, namely sclerokeratitis, iridosclerokeratitis, iridochoroiditis, and choroiditis, probably of tuberculous origin. These eases, which had resisted all the usual methods of treatment, were greatly improved by intravenous injections of salts of gold. In the first 3 cases, 3, 4 and 5 injections, respectively, of 5-10 cg. chrysalbin at intervals of 3-4 days were sufficient to bring about these good results; in the 4th case 30 injections at the rate of one a week caused almost complete disappearance of the lesions. The eoexistence, in all these four eases, of old tuberculous lesions, with negative tests for syphilis, permitted the conclusion that the cases were of tuberculosis origin. Side by side with the classic forms of tuberculosis of the iris and eiliary body there are a large number of other manifestations with more attenuated symptomatology, the etiological diagnosis of which may be in doubt. Many of these cases of torpid and painless iritis and iridocyclitis are accompanied by no appreciable reaction and betray themselves only by a more or less evident diminution of visual acuity, a dull appearance of the iridian membrane and the presence of precipitates. The diagnosis here always remains more or less uncertain, in view of the impossibility of inoculations and of research for the bacillus. However, after elimination of the most frequent causes, certain factors, such as the relatively youthful age, the vascularization of the iris, sometimes even the presence of a slight degree of hypopyon, the slow evolution of the lesions, and the general habitus of the subject, suggest a tuberculous origin. In such cases the excellent effects of the gold treatment will support this diagnosis. Terrien has confined himself to the use of intravenous injections, with deliberate avoidance of instillations and subconjunctival injections, because these have been known to aggravate tuberculous keratitis. Thus, in the rabbit a series of 30 instillations produced large superficial ulcerations of the cornea, which disappeared when the instillations were stopped.-Bulletin de l'Académic de Médecine, January 31, 1933

Indications and Effects of Medicinal Treatment in Association with Carbonated Baths .--It is the opinion of Libensky that a discrimination must be made between diseases which are amenable to carbonated baths and those which prove refractory. The affections for which patients are habitually sent to institutions giving balneotherapy are most frequently (1) mitral or aortic valvular affections, (2) hypertension in the phase of decompensation, and (3) sclerotic nephritis of hypertensive origin. It is in mitral affections that discrimination of cases is most important. An analysis of these reveals that the success of balneotherapy administered alone depends essentially upon the stage which the reactionary modifications of the heart and vessels have reached. This stage can be recognized only with the aid of radioscopy. From this point of view mitral affections can be divided into 3 stages: (1) The silhouette of the heart presents in its ensemble no characteristic enlargement, but the distance from the arch of the aorta to the clavicle is ordinarily diminished, the pulmonary arch lengthened, and its pulsation in profile more marked. Here balneotherapy may of itself produce good effects, by diminishing anhelation and causing regression of peripheral stasis, etc. (2) The arch of the left auricle is longer than that of the aorta and pulmonary artery; it exhibits a weak pulsation, but not always presystolic; the left ventricle is more strongly curved, the contour of the right heart begins to increase, the heart having the appearance of having "turned" upon itself. In this stage the rhythm may or may not be affected. If it is still normal, baths may still suffice to quiet the heart, possibly combined with administration of theobromine. If decompensation has begun, however, the baths must invariably be supplemented by medication. The amount of medica-(digitalin) necessary will be relatively smaller and the results better than if the baths were not used simultaneously. If, however, complete arrhythmia is present, stronger doses must be employed than in normal rhythm. (3) The heart is enlarged in all directions; as a rule, complete arrhythmia of tachycardial type is present. Here the patient should be prepared for the baths by a preliminary digitalin treatment of very energetic character. Only when this has restored conditions to a satisfactory state should balneotherapy be expected to produce any effect. Carbonated baths are of little use in aortic affections. In pure, uncomplicated hypertension they can be dispensed with, any improvement observed from their use being chiefly objective. In hypertension with cardiac or renal complications, however, their employment is advisable when combined with appropriate medicinal therapy, according to the case.—Bulletin de l'Académie de Médecine. January 3, 1933.

Spontaneous Hyperinsulinism.—After brief reference to the literature on spontaneous hyperinsulinism, C. L. Derick, C. F. Newton, R. Z. Schulz, M. A. Bowie, and N. A. Pokorny report the following case: A woman, aged 56 years, who came under observation in May, 1927, gave a history of having suffered, since 1924, from attacks of faintness. dizziness, and inability to walk straight. She did not entirely lose consciousness, and had found that the attacks could be prevented or aborted by taking a glass of malted milk. The diagnosis, at first, lay between neurasthenia, epilepsy, and cerebral tumor. After disappearing for a time, she was admitted to the hospital in March, 1928. Roentgenograms gave no evidence of intracranial tumor. The fasting blood sugar on two different occasions showed 65 and 58 mg. per cent of sugar. She was discharged with the diagnosis of hypoglycemia, cause unknown. She continued on a regimen of three glasses of malted milk daily in addition to her meals. She returned to the hospital about a year later, stating that her attacks were becoming more frequent, and she had grown more helpless and irresponsible. After another thorough examination, it was concluded that she suffered from periodic attacks of hyperinsulinism secondary to a tumor of the islet cells of the pancreas. Further tests were made and operation was finally decided upon, and performed in May, 1930. A tumor, ovoid in shape, and measuring 1.6 by 1.2 cm. was removed with the tail of the pancreas. The tumor was completely encapsulated. The pancreatic tissue was normal in appearance. The tumor was composed of epithelial cells supported by a vascular stroma with only a slight amount of connective tissue. The tumor cells were somewhat larger than those of the islands of Langerhans and among them there were occasionally cells in various stages of degeneration. No mitotic figures were found although cells with hyperchromatic nuclei were not infrequent. Acid granules were not encountered. The acinar and duct elements revealed no morbid changes. A fragment of the fresh tumor was macerated in physiological salt solution, and the supernatant fluid injected intravenously into a rabbit. Blood sugar determinations made at half hourly intervals after the injection gave values of 170, 70, 90, and 120 mg. per cent. This demonstrated that the tumor was very rich in insulin or a substance which gave a pronounced insulin effect. The patient is the oldest (57 years) on record in whom a neoplasm arising from an island of Langerhans has been found, and one of the few cases in which the benignity of the tumor was unquestioned. She made a good recovery, the blood sugar became normal, and the attacks have been entirely absent since the operation .- New England Journal of Medicine, February 9, 1933, ceviii, 6.

LEGAL

PHYSICIANS—GOOD-WILL OF PRACTICE NOT SUBJECT TO TAXATION AT DEATH

By LORPNZ J BROSNAN, LSQ Counsel Medical Society of the State of New York

An interesting point has several times come be fore the courts involving the question of the value and transferability of a physician's personal practice, both during his lifetime and after his death a number of cases in this country and in England hold that a doctor may sell his practice and its good will, and where the selling physician does not live up to the terms of his agreement the purchaser may resort to the courts to enforce the benefits of such contract.

Some years ago in such a case the contention was made that the sale by a professional man of ins good will was void as an illegal restraint of trade. The courts however, overruled this contention and upheld as valid a contract whereby one physician had agreed to turn over his practice and its good will to another doctor and further agreed to no longer engage in practice in the same community.

The question line also arisen as to the right of the State upon the death of a physician to assess a transfer tax upon the good-will of his practice In the case under consideration the deceased, a physician, was one of the pioneers in the field of roentgenology He had devoted most of his career to the specialty and had also invented and prefected improvements in the mechanical and chemical processes involved in the use of the He had been known as a lecturer on the subject, and his ability was known and recog nized widely In his practice he had two as sistants, and by the terms of his will he be queathed his apparatus and equipment and also his good-will to his assistants, one a doctor and the other a technician After the decedent's death, the doctor who had been his assistant leased the same offices and continued in practice. removing the decedent's name and substituting his own name

In the proceedings settling the estate, the transfer tax appraiser put a value upon the good-will of the practice of some \$38 000. The executors appealed from the order assessing the transfer tax upon the sud item, squarely presenting for determination the question of whether the good-will of the practice and business of a man who has attained eminence in his profession has, upon his death, a value that is capable of ascertainment or computation. The Surrogate in a ruling subsequently affirmed by the Appellate Division, determined that the case presented was not one

where the good-will of a business or profession of a decedent could be taxable after his death. The opinion of the Surrogate set out as reasons why the good-will of the decedent did not pass upon his death to his successor the following

"The extensive and lucrative business trans acted by the decedent was the result of his repu tation for great skill in taking x-ray pictures, and as this skill and knowledge died with him it could not constitute an element of good will that would survive him. The death of a man who had attruncd such priminence and reputation as a roentgenologist must have received such publicity as would bring it in the attention of practically all the members of the medical profession who knew him by reputation or who would ordinarily have sent patients to him Therefore, after his death those doctors would not send any more patients to the office theretofore conducted by him, and if the office passed into the possession of another doctor or rocntgenologist, it could scarcely be said that its former occupancy by the decedent made it more valuable to his successor succeeded in the office by Dr I, but the business was conducted under the name of Dr I, and the name of the decedent was not used in connection with it

"The skill and knowledge which Dr I acquired during the years of his association with the decedent, and which induced physicians to send their patients to him, were entirely personal to him, and were not transferred to him by the decedent as part of the good will of the business. The reputation which the decedent had acquired was personal to him, and it was not due to the place where he maintained his office or to any trade mark or trade name."

In his opinion the Surrogate acknowledged the fact that a doctor might during his lifetime, for a valuable consideration sell his practice and goodwill but distinguished from that situation the situation presented upon a doctor's death. He said

"** * * there seems to be a distinction between the business sold by a doctor during his lifetime and the value of that business after his death If sold during his lifetime, he could introduce the purchaser to his patients and friends as a prudent and reliable physician, and such introduce tion would immediately give the purchaser a reputation and standing which otherwise might require years to establish. It seems to me that such introduction and recommendation to patients constitute the real consideration for the money paid to a retiring professional man by one who wishes to succeed him. But after a man who has acquired a reputation for great skill or knowledge is dead persons who would go to his office for the purpose of consulting him and availing themselves of his superior skill would not go there merely because the office was still open and occupied by another person who had no reputation for superior knowledge or skill. The name of a physician who is prominent in his profession is known to the public generally although few of them may know where he maintains his office. If any person should require his services they would have no difficulty in obtaining his office address from the directories. It is not, therefore, where he practices that is important—it is the reputation which he has attained. But that reputation is necessarily personal to him; it is built upon his personal achievements; it is independent of the location of his office or his assistants. When he dies the fact is usually brought to the attention of the public, and if persons should thereafter require the services of a physician skilled in the particular branch of medicine or surgery with which the deceased physician had been identified, he would not ordinarily go to the office that was maintained by that physician in his lifetime, but would consult some other physician who was regarded as a specialist in the same line of work."

The court stated that one of the tests for determining whether the decedent left to his successor anything of taxable value, was to consider the case that would result if some unknown and inconspicuous physician took over the office that Dr. I had taken, putting his own name on the door. The Surrogate asked the question as to whether, under such circumstances, any considerable number of the decedent's clients would con-

tinue to come to that office. The answer, the Surrogate said, in his opinion was that it was highly improbable that such a person would receive any patients who had patronized the decedent because of his exceptional skill and knowledge. The Surrogate also made clear that he felt that the specialty of roentgenology was such that a man obtains employment from his own patients and from other doctors, primarily because they "know him personally and have special confidence in his skill and knowledge of such profession."

The Surrogate also noted in his opinion that much of the success of Dr. I may have been the result of his association with the decedent, saying:

"The appraiser's report shows that Dr. I, who was an assistant of the decedent, and who occupied his office after his death, did a reasonably profitable business, but the evidence shows that Dr. I, because of his association with the decedent, had acquired considerable skill in making x-ray examinations, and he became well and favorably known to the physicians who were in the. habit of sending patients to the decedent. The special knowledge of roentgenology which Dr. I acquired was probably due, to a considerable extent, to his association with the decedent in the conduct of his business, and the opportunities for becoming acquainted with physicians who usually sent their patients to be x-rayed were also due, in no small measure, to his association with the decedent. But they were both acquired during the lifetime of the decedent, and could not have been transferred to Dr. I by the will of the dece-

The holding of the Surrogate, in addition to being a distinctly sound one, is a source of considerable satisfaction for it recognizes that the practice of medicine is regarded in legal contemplation as a profession primarily founded upon the skill and ability of each individual practitioner.

TREATMENT OF LACERATION OF PALM

A doctor engaged in the general practice of medicine was consulted about midnight by a young woman who explained to him that she had hurt her hand by falling. The doctor removed the handkerchief which was tied around the left hand, and on examination found a laceration of the palmar surface, which laceration was uneven and jagged and approximately one and one-half inches in length. The doctor immediately treated the patient by thoroughly washing the surface of the wound with lysol, making the wound clean, painting it with iodine and applied a sterile bandage.

The patient was next seen the following morning when substantially the same treatment was repeated, and the patient was directed to return the next day. The doctor continued to see the

patient daily for about ten days and on each occasion he dressed the wound which progressively improved. On each of these visits the fingers of the injured hand were found to be perfectly normal

Although the patient was told to return for further treatment, she did not do so and was not seen by the doctor until about three weeks later when he happened to meet the girl. At this time he examined the wound and found that one of her fingers was somewhat flexed by reason of contraction of scar tissue formed in the healing of the laceration. The patient, however, refused to have any more treatment given by the doctor.

An action was commenced by this patient against the physician sometime later, in which

the claim was made that the doctor had failed to properly treat the plaintiff's injuries, as a result of which one of her fingers had become defective, crippled and erooked and that the free use of said finger was impeded. The case came on for trial before a judge and jury, and at the close of the testimony put in on behalf of the plaintiff a motion was made to dismiss the complaint on the ground that plaintiff had failed to prove her cause of action, and the court granted said motion, thereby terminating the matter in favor of the doctor.

ALLEGED NEGLIGENT ADMINISTRATION OF

A middle-aged woman consulted a doctor who specialized in physiotherapy, complaining of pain in the shoulder.

Examination resulted in a diagnosis of bursitis. He suggested electric treatment, to which she consented and he administered to her a halfhour treatment using a Wappler Teletherim In administering the said treatment the doctor saturated two towels with saline solution, fastening one over her shoulder and the other around her body. To each of these towels were applied tinfoil pads connected by wires to the machine. Six such treatments were given at intervals of every second day. A seventh treatment was undertaken and on this occasion, after the patient had been exposed to the electric current for about five minutes, she complained of heat in the shoulder. The doetor reduced the current and the patient stated that she felt all right and requested him to go alread with the treatment as before. When he again turned on the current to its usual intensity, the patient again complained of heat. The doetor then shut off the current and removed the bandages and readjusted them, after which he again administered a ten-minute treatment. Again the patient complained of heat and on this occasion the doctor took off the bandages and observed a reddened spot on the shoulder at a point under one of the poles. He dressed the said area and the patient went home, returning in a few days complaining that a burn which appeared to be a second degree one had developed. She told him that she wanted no more treatments and that she was going to her family doctor who would take over the eare of the case.

The doctor heard no more of the matter until an action was instituted against him, charging that he was negligent in his treatment of the case and further charging that the burns that the plaintiff received had required more than six weeks to heal and that a large circular scar about three inches in diameter remained on her shoulder as a permanent disfigurement.

The case came up on the Calendar and when it was about to be reached for trial the plaintiff's attorney agreed to discontinue the matter, thereby terminating the same in favor of the doctor without trial.

BROKEN ASPIRATING NEEDLE

A general practitioner was consulted by a young man who complained of pains in his cliest. The doctor after examination diagnosed his case as pleurisy with effusion, gave the man a prescription, directing him to go to bed, and telling him he would call at his home in a few days. The doctor did so taking with him an assisant. patient was found in bed and after examination the doctor decided to aspirate his pleural cavity, by the use of an aspirator with pump and needle equipment. After the needle and syringe had been sterilized in boiling water the man was eaused to sit in a chair. The needle was inserted between two ribs below the shoulder and with the aid of the assistant the doctor pumped a large amount of pus from the patient. As the doctor prepared to remove the needle it snapped at the hilt and about two inches of it disappeared into the muscles. The doctor sterilized a scalpel and incised at the spot where the needle had disappeared. The doctor probed in vain for the needle

for some time. The patient was then directed to enter a hospital for operation. The case was turned over to a surgeon. X-rays were taken which showed the location of the needle. The surgeon made an attempt to remove it under a fluoroscope, but it could not be located. The patient remained under the surgeon's care for further treatment for the condition of empyema. When discharged the needle was still in the patient's cliest.

A suit was brought against the general practitioner, charging him with negligence in permiting the needle to break and to remain in the plaintiff's body. The case finally came on for trial and the defendant appeared by his attorney, ready to defend the action. The plaintiff's attorney appeared and told the court that he could not locate his client, and asked that the case be adjourned. The case had already been adjourned previously for the same purpose, and on motion of the defendant's attorney the action was dismissed.

NOTES NEWS

FINAL ANNOUNCEMENTS OF THE ANNUAL MEETING

The preparations for the Annual Meeting of the Medical Society of the State of New York, on April 3-5, in the Waldorf-Astoria, New York City, have been developed to a greater extent and completeness than ever before, and have been published in the Journals of March first and

March fifteenth. The two announcements which follow complete the arangements, so far as they may be foreseen and outlined. The program is attractive and practical from beginning to end, and will appeal to members of every tempera-

RADIO SCHEDULE OF THE ANNUAL MEETING

A radio broadcasting program of thirteen addresses from eight stations has been arranged for the Annual Meeting of the Medical Society of the State of New York. The subjects will be those which are frequently discussed by the people, and which therefore have a news value. The speakers will be outstanding leaders in those medical activities in which the public has an active share and responsibility. The complete schedule is as follows:

Station WABC-485 Madison Avenue.

Monday, April 3—5:15 p.m.—15 minutes.

Subject, "Recent Advances in Child Welfare."

Speaker, Dr. G. F. McCleary, A Deputy Senior Medical Officer of the Ministry of Health, Great Britain.

Wednesday, April 5—5:00 p.m.—15 minutes. Subject, "Cancer and the Community."

Speaker, Dr. Burton J. Lee, Professor of Clinical Surgery, Cornell University Medical College.

Station WEAF-711 Fifth Avenue.

Monday, April 3—3:00 p.m.—15 minutes.

Subject, "The Doctor-Fact and Fiction."

Speaker, Dr. Chas. Gordon Heyd, President of the Medical Society of the State of New York.

Tuesday, April 4—2:45 p.m.—15 minutes.

Subject, "The Costs of Medical Care." Speaker, Dr. Arthur W. Booth, Member of

the Board of Trustees, American Medical Association.

Station WJZ—711 Fifth Avenue.

Wednesday, April 5-4:30 p.m.-15 minutes.

Subject, "Children and Their Hearts."

Speaker, Dr. William D. Stroud, Associate Professor of Cardiology, Jefferson Medical College of Philadelphia.

Station WOR-1440 Broadway.

Wednesday, April 5-4:45 p.m.-15 minutes. Subject, "The Health of the State."

Speaker, Dr. Thomas Parran, Jr., Commissioner and Executive Health Officer, State Department of Health, New York.

Station WNYC—Room 2510—Municipal Build-

Wednesday, April 5—11:20 a.m.—12 minutes. Subject, "The Story of Insulin."

Speaker, Dr. Charles H. Best, Professor of Physiology, University of Toronto.

Wednesday, April 5-7:00 p.m.-10 minutes. Subject, "Rheumatism and Arthritis."

Speaker, Dr. Russell L. Cecil, Asst. Prof. Clin. Medicine, Cornell University Medical College.

Station WINS-114 East 58th Street.

Monday, April 3—10:00 a.m.—15 minutes.

Subject, "Standards of Medical Practice."

Speaker, Dr. Frederic E. Sondern, Treasurer of the Medical Society of the State of New York.

Tuesday, April 4—10:00 a.m.—15 minutes.

Subject, "The Goiter Patient."

Speaker, Dr. Frank H. Lahey, Surgeon, New England Deaconess and New England Baptist Hospital, Boston, Mass.

Wednesday, April 5-9:30 a.m.-15 minutes. Subject, "Gall-Stones."

Speaker, Dr. Lester R. Whitaker, Visiting Surgeon, Memorial Hospital, Boston, Mass.

Station WEVD-Hotel Claridge-44th Street and Broadway.

April 4-4:45 p.m.—15 minutes.

Subject, "Your Eyes At Forty."

Speaker, Dr. Arthur J. Bedell, Chairman of Scientific Work, Medical Society of the State of New York.

NEWS NOTES

467

Statinn WLWL—425 West 59th Street. Wednesday, April 5—6:15 p.m.—10 minutes. Subject. "Diabetics and Their Doctor." Speaker, Dr. Elliott P. Joslin, Clinical Professor of Medicine, Harvard University Medical School, Boston, Mass.

DEMONSTRATION OF WORKMEN'S COMPENSATION ARBITRATION

The Bureau of Compensation Arbitration of the New York County Medical Society will hold its regular meeting on Thesday, April 4th, at 3 o'clock, in the Pillemont Suite on the fuurth floor of the Waldorf-Astoria Hotel. Dr. Morris Rosenthal, Director of the Bureau, announces that the meeting will be a conference of the members of the Bureau with representatives of the Compensation Insurance Companies, for the purpose of discussing and arbitrating specific cases of disputes between the attending physicians and the insurance companies. Members of the Medical Society of the State of New York are invited

to be present and to witness the procedures which have been in successful operation in New York County for over twn years, during which time more than six hundred cases have been arhitrated and settled.

This is an opportunity for the chairmen and members of the Economic Committees of County Medical Societies to attend an actual arbitration "chinic," and to meet the physicians representing the insurance companies. The procedure will be informal, and visiting physicians will be encouraged to take part in the discussions and to ask questions on their own problems.

LEGISLATIVE BULLETIN NUMBER 10

Legislative Bulletin Number 10

March 17, 1933.

Hearings

March 22nd—Assembly Committee on Ways and Means.

Assembly Int. No. 329—Colien, Workmen's Compensation Law, creating commission on

Action on Bills

Senate Int. No. 426—Twomey, habit-forming drugs, passed the Senate and has been referred to the Education Committee in the Assembly.

Assembly Int. No 772—Doyle, bichloride of mercury, passed the Assembly and has been referred to the Codes Committee in the Senate.

Assembly Int. No. 1970—Brownell, Workmen's Compensation Law, immates of charitable institutions, has been advanced to third reading in the Assembly.

Assembly Int. No. 784—Robinson, expert psychiatrists, has been reported out of committee in the Assembly.

Assembly Int. No. 705—Austin, Health Department rules, has passed the Assembly and been referred to the Health Committee in the Senate.

Senate Int. No. 487—Esquirol, Health Department rules, has passed the Senate and been referred to the Health Committee in the Assembly.

New Bills Introduced

Senate Int. No. 1556—Esquirol; Assembly Int. No. 2095—Austin, to amend the Mental Hygiene

Law generally. Referred to the Health Committee.

Senate Int, No. 1589—Buckley; Assembly Int, No. 2126—Dunkel, enacts alcoholic beverage control law, appropriating \$100,000 for expenses of state control board of five members to be selected from an eligible list of twelve persons, three of whom shall be physicians nominated by the Council of the Medical Society of the State of New York. Referred to the Finance Committee, Recommended by the State Liquor Control Commission.

Senate Int. No. 1590—Buckley; Assembly Int. No. 2125—Dunkel, adds new articles to the Tax Law, providing for an excise tax on beer; \$50,000 of the revenue to be paid yearly to the Education Department for temperance education. Referred to the Finance Committee. Recommended by the State Liquor Control Commission.

Senate Int. No. 1596—Dunnigan, adds new article to the Tax Law, creating an excise bureau in the State Tax Department. Referred to the Excise Committee.

Copics of these three bills are being mailed to you today under another cover.

Assembly Int. No. 2035—Breen, amends the Public Service Law, empowering the commission to require operators of all omnibuses to be physically and mentally qualified to perform duties. Referred to the Public Service Committee.

The hearing on the antivivisection bills was as satisfactory to us as in previous years. It was a very dignified affair so long as the physicians

were testifying, but when the proponents took the stand, dignity withdrew. The arguments advanced in support of the bill were as fallacious, inaccurate, and emotional as in previous years. The proponents of the Bernhardt bill asked for a postponement of one week for the privilege of submitting their evidence, on the ground that they found it impossible to get their "doctors" to come to Albany on the 14th. The committee graciously granted them permission to introduce three physicians on Tuesday, March 21st.

Dr. Sondern, Chairman of the Committee on

Medical Research, brought to Albany for the hearing Drs. Peyton Rous and Florence Sabin, from the Rockefeller Institute; Dr. John Wyckoff, from Bellevue; and Drs. Whipple and Morton, from the University of Rochester. In addition, Commissioner Parran, Dr. Wadsworth, and Dr. Mackenzie, of Cooperstown, and Dr. Schiff of Plattsburg, were present. The latter two represented the New York State Association of Public Health Laboratories.

HARRY ARANOW, Chairman.

KINGS COUNTY

The program of the monthly meeting of the Medical Society of the County of Kings held on the evening of Tuesday, February 21, was as follows:

Address: "Common Ground in the Next Steps for the Medical Profession and the Profession of Social Work," Bailey B. Burritt, M.A., New York City.

Address: "Compulsory Health Insurance

Abroad," Emil Koffler, M.D., Bronx.

Address: "The Problems of Medical Practice and the State Society," Chas. Gordon Heyd, M.D., F.A.C.S., New York City.

Friday Afternoon Lectures: The Friday Afternoon Lecture Series for March, 1933, is as

follows:

March 3rd—Dr. Charles H. Andrew will discuss "The General Practitioner and Eye Conditions." We shall be happily informed as to conditions which we should recognize and care for, and also that other group of eye conditions which we should recognize when they are present but which we should not attempt to handle ourselves.

March 10th—Dr. Frank B. Cross will present "The Patient with Nephritis." A happy title, as Dr. Cross considers the patient primarily rather than the pathology. We shall be told how to care for the individual rather than merely to treat for a physiological breakdown.

March 17th—Dr. Joseph B. L'Episcopo will speak on "Disabling Feet." How often the cry—"My dogs sure ache!" Our speaker will tell us all about the why, the wherefore, and what to do

about it.

March 24th—Dr. E. Jefferson Browder will discuss "Head Injuries." Dr. Browder will give, in his usual clear manner, a consideration of head injuries—what to do and what not to do . . . what constitutes good treatment and what is "meddlesome interference."

March 31st—Dr. Max Goldzieher will present the subject of "Physiology and Pathology of the Pituitary Gland and Their Clinical Aspects." This may sound somewhat highbrow but pituitary disturbance is a real condition to the one suffering from it and we must know how to recognize pathology of this endocrine when present.

Radio Broadcasting: The Subcommittee on Radio Broadcasting of the Committee on Public Health wishes to report that medical talks prepared by members of the County Society for broadcasting were forwarded upon request to the American Medical Association. To date nine of these talks have been rebroadcast by the Bureau of Health and Public Instruction of the American Medical Association. These talks have also been supplied to other county medical societies throughout the United States by the American Medical Association. The Medical Society of the State of Wisconsin has also broadcast one of our talks.

Assistance in the preparation of radio talks will be given gladly by the Subcommittee on Radio Broadcasting. It is a ruling of the State Committee on Press Publicity that all talks must be submitted to the committee before broadcasting.

The Committee on Public Health suggests that the medical profession would be interested in the series of radio talks entitled "Gripping Moments in Medical History," over Station WEAF at 4:30 on Sunday afternoons, and the "History of Medicine," over Station WEAF at 7:15 Sunday evenings. The Committee on Public Health will appreciate receiving the comments of the medical profession on these programs.

Health Talks: Health talks are being given every Monday evening at 9:00 o'clock by members of our Society at the Eastern District Y. M. C. A. Similar talks are being given at the Navy Y. M. C. A. The Subcommittee on Radio Broadcasting is furnishing the speakers. If you have a subject to present before a lay organization, send it in to the committee with a note telling your available hours of the day and the day of the week you prefer, thus assisting the com-

mittee in meeting requests for speakers that may be made in the future.

The Library: Nineteen thirty-two witnessed the biggest year in the use of our library. The daily statistics kept show that 12,538 readers consulted 50,164 books in the library and borrowed for home use 9,327 publications. This is an increase of 18 per cent in the number of readers, 30 per cent in the number of books consulted, and

43 per cent in the number of books taken out, as compared with 1931.

As far as an appraisal can be made from statistics, this record indicates the value and usefulness of this activity of our Society. The greatly increased use has added considerably to the work of our staff. This has been carried on by the same number of workers in addition to the other duties in the daily routine of the library.

MONROE COUNTY

The February News Letter of the Medical Society of the County of Monroe contains the following news notes:

Costs of Medical Core Considered: A hearing on the report of the National Committee on the Costs of Medical Care by the Comitia Minora acting as the local Committee on this question, was held on January 17, 1933, with an attendance of fifty-seven physicians. The opinion was expressed by some that the question of group insurance for either hospital or medical care should not be lightly brushed aside. The view was expressed by others that some type of group insurance could be developed which would not disrupt the traditional relationship between doctor and patient, and which would not exploit either patient or doctor for private gain, and which would not introduce the element of politics into medical practice. The consensus of opinion, as expressed, was that it is desirable to enhance the value and importance of the family physician, and that it is eminently desirable to emphasize and retain the personal relationship between patient and family physician.

Referring to the increasing amount of free service being given by physicians, the view was expressed that unless reimbursement for this service was made by the State, no other form of payment was probable. It was the consensus of opinion that the County Medical Society should continue to view the entire question with an open mind, and feel free to call upon lay organizations in order to obtain their point of view; and should welcome any help if there was any assurance that such help might result in a solution of this difficult problem.

Dispensary Admissions: At a joint meeting of the members of the Academy of Medicine and the Medical Society of the County of Monroe held on January 25th, attended by 206 physicians, the question of dispensary admissions was considered. The speaker, H. Van Caldwell, Executive Secretary of the Academy of Medicine of Cleveland and the Cuyahoga County Medical Society, discussed the plan of dispensary admis-

sions in operation in Cleveland, Ohio, and stated that the dispensaries there found themselves overburdened with a new group of patients who in the past were able to care for their medical needs and who in the future may again be able to do so.

The thought behind the Cleveland plan is that all patients who in normal conditions could inance their medical needs should at the present time be referred to private physicians of their own choice before they are accepted as dispensery patients. The plan is under the joint supervision of the medical societies, the hospitals, and social agencies.

In a discussion by hospital directors present and practicing physicians, it was the consensus of opinion that this question of dispensary admissions should be further considered by all interested agencies with the general welfare of the whole community in mind.

The joint Committee in charge of this study is continuing its work, and conferences will be held with representatives of interested agencies.

Doctors' Hobbies: At the March meeting of the Academy of Medicine, there will be held an exhibition of the hobbies of the various doctors of the community. The exhibition will include such things as doctors may make or collect, such as oil and water colors, charcoal drawings, photographs, ship models, jewelry, musical instruments, stamps, rare books, guns, and so on. Notable exhibitions of this sort are held each year by both the New York and the Toronto Academies of Medicine.

Academy Library Notes: Members are requested to save all old journals, except the J.A.M.A., for the Library of the Academy. They will be used to exchange with other libraries. The State Journal is particularly needed.

The Library needs proceedings and transactions of any medical society of any year. If you have any copies not in use, please give them to the Library.

 Phone in any reference you wish to have looked up and the librarian will have it ready for you when you come in.

RENSSELAER COUNTY

The Medical Society of the County of Rensselaer had a lengthy and enthusiastic discussion on the report of "The Doctor and the Free Clinic" Committee, at their regular meeting on February 14, 1933. The entire evening was given over to the subject. It was expected to introduce the "Costs of Medical Care for the American People" report, but no time was left for the subject.

"The Doctor and the Free Clinic" Committee submitted a detailed report of the annual free public medical service rendered by the doctors of the country. According to the statistics given by the committee it was disclosed that the clinic doctors cared for more than 18,257 patients during 1932, not one of whom could have received the same care as a pay patient for less than \$2.00, and many of whom would have had to pay more than \$100.

This means that in Troy, with a population of less than 75,000 people, approximately one out of every five people have received free medical care during 1932. The physicians believe that the clinic privileges are being abused; and the committee was authorized to continue its work and also to make a study and report on the final report of the National Committee on the Cost of Medical Care.

The Trov Record of February 15, 1933, published an excellent summary of the report, which was well adapted to inform the public of the free contributions of the physicians to the relief of physical suffering and distress. The Record said:

"In its survey of clinical problems in the city, the Society stresses the point that this clinical work, now efficiently organized, will not in any way be curtailed. It is the Society's belief that when poverty and unemployment are prevalent it is a bad time to curtail or in any manner hamper charity work among the physicians."

The Medical Society of the County of Rensselaer met at the Troy Hospital on March 14th and adopted a widespread plan of action in regard to the dispensing of free medical care to the people of the county.

From a previous report it was shown that considerably over 18,000 patients are receiving free medical care at our public clinics each year. With Troy's population of less than 75,000 it was pointed out that our indigents are either relatively larger than usual, or people are visiting the clinics and receiving free care when they are able to pay for a doctor.

With this in mind, and in order to provide for a more even distribution of the charity work done by the physicians, the society recommends the adoption of a new card system by every clinic in the county. According to the plan, each new patient who applies for care at the free public clinics will be given a yellow card which the patient will be required to take to a physician of his own choice. This family doctor will then either care for the patient as his own private charity case; or will issue a red card recommending the patient to the clinic for free medical care.

By this method, patients will have a wider range of selection of doctors, and will many times be saved the embarrassment of having to wait in an open public clinic, to be cared for by a doctor not of their own choice.

It was made clear that the physicians of Rensselaer County realize that everyone is entitled to receive adequate medical care; and ample provision is being made for such care by their private as well as public beneficent efforts.

The resolution adopted by the Society read as follows:

WHEREAS, The attendance at the Free Public Clinics in Troy is already assuming vast proportions and it is evident that such attendance may continue to increase in view of the present economic depression; and

WHEREAS, For many years past it has been demonstrated that individual selection of physicians by the laity is the essential element of proper medical care; and

WHEREAS, It is the desire of the members of the Medical Society of the County of Rensselaer that the Free Public Clinics shall not overlap other medical eifort, and that each physician of the county is ready to assume his share of the economic burden; therefore be it

RESOLVED: First: That our secretary have printed an ample supply of yellow cards suitable for patients to take from a clinic to a physican of their choice requesting his opinion on their eligibility for admittance to the clinic; also an ample supply of red cards suitable for physicians to use in recommending patients to the free

Second: That our secretary supply the members of the society with the red cards and explain to them that on and after April 1st, 1933, it is the request of the Medical Society of the County of Rensselaer that no new patient be admitted to any of the free public clinics of the county of the request of the county without this pour line and the request of the county without this pour line and the request of the county without this pour line and the request of the request o ty without this card signed by the patient's family physician.

Third: That our clinic committee be requested to interview the sponsors of Free Public Clinics and explain the plan and purpose of the card system; and

Finally, That the name of any member of the Society who willfully violates the provisions of this act be referred to the board of censors.

The following scientific program of the meeting was carried out by the hospital staff:

"Carcinoma of Penis," Dr. J. H. Reid.
"Juvenile Hypertension," Dr. H. V. Foley. "Complicated Cataract," Dr. J. D. Carroll.
"Extra-Uterine Pregnancy," Dr. C. R. Lewis
"Coronary Thrombosis," Dr. G. D. Hoffeld.
"Gumma of Penis," Dr. J. J. Curley.

WM. B. D. VAN AUKEN.

THE DAILY PRESS

COMPULSORY HEALTH INSURANCE

The New York Times of March 17 carried a first page news note on the annual meeting of the Milbank Fund, in the New York Academy of Medicine on March 16, and said:

"Compulsory health insurance on a State-wide basis was urged last night by Albert G. Milbank, president of the Milbank Memorial Fund, at the annual dinner of the fund at the New York Acadeny of Medicine. The dinner was attended by leaders in health and social welfare work.

"Mr. Milbank deelared that the time was ripe to ask State Legislatures to adopt health insurance plans, with contributions from employers and employes, to become effective as soon as employment and business activity would permit. The eventual creation of unemployment reserves, he added, should complete the social insurance program.

program.

"The States should be asked to provide for the appointment of representative commissions, which, through coordinated efforts, would work out a detailed plan of operation,' he continued. I would like to see the new Secretary of Labor,

with her unique experience and rare talents, act as a sponsor for a conference of such State commissions, if appointed, or of representatives of the States if such commissions are not appointed, to insure the maximum uniformity as to plans that will not only benefit labor but at the same time be helpful and not harmful to the general financial structure of the country.

"'The plan should be based on certain fundamental principles. It should be reasonably adequate to meet the strain that will be put upon it; it should be on a contributory basis and, for the same reasons that the employe's contribution should be limited to a percentage of his wages when received, so the contribution of the employer should be limited to a percentage of profits when earned; lastly, the part to be taken by the State should be restricted to supervision and regulation.'

"The voluntary form of insurance recommended by the Wilbur Committee on the Cost of Medical Care, Mr. Milbank said would not produce the results contemplated."

SPECIALISTS

The New York *Times* of February 15 comments editorially on the medical specialists as follows:

"Economists are not the only profession interested in the Law of Diminishing Returns. The doctors and the college presidents, to name only two gainful occupations, are taking note of its effects. But it does not always have the same name. Sometimes it is the swing of the pendulum. Sometimes people say that what has gone up must come down. In this sense all life is subject to the principle of Diminishing Returns.

"The doctors have been giving too much thought to the problem of the specialist versus the general practitioner. The annual Congress on Medical Education opened at Chicago the other day with a full-length debate on the menace of the ill-trained 'specialist.' But a cheerful view was taken by one speaker who argued that it won't be long now before every medical specialty will have reached its saturation point. 'This may result in the development of a type of general practitioner better trained than the graduate of today.'

"When medical practice has split up into a mass of narrow specialties, the time will obviously have come for a liaison officer or coordinator. He will be the general practitioner; once more illustrating the Law of Diminishing Returns."

INDIVIDUALISM

Individualism is essential in the practice of medicine, but it is essential in all human endeavor, as is shown in the following editorial in the New York Times of March 2:

"The merits of traditional American individualism as against public enterprise were debated yesterday in addresses at a luncheon of the Advertising Club of New York by Dr. Virgil Jordan, president of the National Industrial Conference Board, and Professor Walter Rautenstrauch of the Department of Industrial Engineering of Columbia University. "Dr. Jordan said it was absurd to expect government to run industry 'when in the present emergency, government cannot even feed, house and clothe the destitute or protect the public against robbery through bank failures.' He was not attacking individual public officials, he remarked, but was pointing out that 'everything creative is done by somebody and not by everybody.'

"The only revolution today,' he continued, 'is in the direction of greater individualism exempli-

fied by the back-to-the-land movement and the decay of big business, the growth of small enterprises. It is a decentralizing movement.'

"Although there might be an increase in public control of utilities and banking, he predicted the greatest period of individualistic enterprise ever

seen lies just ahead.

"'No administration can do for us,' Dr. Jordan asserted, 'what we don't do for ourselves. The "new deal" may reshuffle the pack, but the game will remain the same.'"

NARCOTICS IN TURKEY

The New York Times of February 28 has the following editorial comment on the advanced stand taken by Turkey for the control and the production and sale of opium and other narcotics:

"Of a Christmas gift to humanity by Turkey little note has been taken in the midst of the ills that have befallen the world. On that day at the Cabinet meeting, presided over by President Mustapha Kemal, Turkey took her stand with the United States and eight other countries in ratifying the opium conventions of The Hague 1912 and 1914 and of Geneva 1925 and 1931. Under the draft laws adopted for submission to the Grand National Assembly, cultivation of drugproducing plants will be supervised and limited, all private factories that have been manufacturing narcotic drugs will be closed, and the manufacture of such quantities as are required for medical purposes in Turkey and elsewhere will be entrusted

to one factory owned and managed by the Government. The export of opium will be confined to a semi-official organization under Government control.

"That this step has been taken at the instance of the Gazi gives assurance that it will be adopted by the Assembly and rigorously enforced. Turkey has been, according to the narcotic reports of the League of Nations and of the United States Treasury, the worst offender in the export of opium. Her move in the other direction is the more to her credit, since it can hardly be to her commercial advantage. She has even anticipated some of the foremost European nations in this wholesome policy, for England, France, Germany and Italy have not yet ratified the 1931 Geneva Convention. It would appear from the reports that America had some influence upon Turkey in determining upon this course of action."

RESEARCH REGARDING BLUSHING

The research workers in the psychology department of Colgate University have made extensive investigations of the problem of sleep, and are now searching for the cause and means of control of blushing, as is shown in the following editorial in the New York Herald Tribune of February 28:

"Whatever may be the psychological secrets behind the blush which rises from time to time to the faces of most humans, they are about to be plumbed with scientific precision for the edification of a waiting world. The master minds of Colgate University's department of psychology are about to make an intensive study of the flush which mounts the cheeks in moments of embarrassment, happiness or discovered guilt, and to this end they have broadcast a questionnaire, preparatory to a monumental blush report. Do you blush when praised or ridiculed, in the presence of persons of the opposite sex or in crowds, when happy, offended or upon hearing smoking room

anecdotes? And when you blush do you blush a little or plenty, feel faint, fidget with your hands, break into a sweat, adjust your tie or try to run away? In short, what are the details of your blushing life?

"We hope this blush investigation turns out to be really fruitful and, most of all, that it will disclose some method of preventing at will the betraying rush of blood to the face which has served us to no good end any number of times. Stuttering and stammering can be conquered by patient training; fidgeting, fiddling and watch chain twirling can be mastered by intense effort and application, and if these psychologists are worth their salt they'll find a blush prevention treatment. The gestalt theory, behaviorism and inferiority compensation can, for the moment, be neglected, but if the science of the mind is going to justify its existence it will grapple with and dispose of this manifestation if for no other reason than to render obsolete the cliché of the blushing bride.

NARCOTICS IN TURKEY

The New York Times of February 28 has the following editorial comment on the advanced stand taken by Turkey for the control and the production and sale of opium and other narcotics:

"Of a Christmas gift to humanity by Turkey little note has been taken in the midst of the ills that have befallen the world. On that day at the Cabinet meeting, presided over by President Mustapha Kemal, Turkey took her stand with the United States and eight other countries in ratifying the opium conventions of The Hague 1912 and 1914 and of Geneva 1925 and 1931. Under the draft laws adopted for submission to the Grand National Assembly, cultivation of drugproducing plants will be supervised and limited, all private factories that have been manufacturing narcotic drugs will be closed, and the manufacture of such quantities as are required for medical purposes in Turkey and elsewhere will be entrusted

to one factory owned and managed by the Government. The export of opium will be confined to a semi-official organization under Government control.

"That this step has been taken at the instance of the Gazi gives assurance that it will be adopted by the Assembly and rigorously enforced. Turkey has been, according to the narcotic reports of the League of Nations and of the United States Treasury, the worst offender in the export of opium. Her move in the other direction is the more to her credit, since it can hardly be to her commercial advantage. She has even anticipated some of the foremost European nations in this wholesome policy, for England, France, Germany and Italy have not yet ratified the 1931 Geneva Convention. It would appear from the reports that America had some influence upon Turkey in determining upon this course of action."

RESEARCH REGARDING BLUSHING

The research workers in the psychology department of Colgate University have made extensive investigations of the problem of sleep, and are now searching for the cause and means of control of blushing, as is shown in the following editorial in the New York Herald Tribune of February 28:

"Whatever may be the psychological secrets behind the blush which rises from time to time to the faces of most humans, they are about to be plumbed with scientific precision for the edification of a waiting world. The master minds of Colgate University's department of psychology are about to make an intensive study of the flush which mounts the cheeks in moments of embarrassment, happiness or discovered guilt, and to this end they have broadcast a questionnaire, preparatory to a monumental blush report. Do you blush when praised or ridiculed, in the presence of persons of the opposite sex or in crowds, when happy, offended or upon hearing smoking room

anecdotes? And when you blush do you blush a little or plenty, feel faint, fidget with your hands, break into a sweat, adjust your tie or try to run away? In short, what are the details of your blushing life?

"We hope this blush investigation turns out to be really fruitful and, most of all, that it will disclose some method of preventing at will the betraying rush of blood to the face which has served us to no good end any number of times. Stuttering and stammering can be conquered by patient training; fidgeting, fiddling and watch chain twirling can be mastered by intense effort and application, and if these psychologists are worth their salt they'll find a blush prevention treatment. The gestalt theory, behaviorism and inferiority compensation can, for the moment, be neglected, but if the science of the mind is going to justify its existence it will grapple with and dispose of this manifestation if for no other reason than to render obsolete the cliché of the blushing bride.

HANDBOOK OF BACTERIOLOGY. For Students and Practitioners of Medicine. By Joseph W. Brocke, M.D. (Dublin) Third edition. 12mo of 459 pages, illustrated, Baltimore, The Williams & Wilkins Company, (William Wood & Company), 1932. Cloth, \$5.00.

This handbook describes the usual bacteria which are of interest to the practitioner. It also contains among others chapters on the preparation of culture media, serological technique, and the bacteriology of water, milk, and shellfish. There is a full description of the theories of immunity and their practical application in claptes on phagocytosis and opsonins, toxin and antitoxins, agglutinins and precipitins, and anaphylaxis. The text, which has been brought up-to-date in this revision, is profusely illustrated and easy to read.

E. H. Nunsu-

THE ADVANCE OF MEDICINE. By The Right Honourable Lord Mounthan, K.C.M.G., C.B. 16mo of 64 pages. New York and London, Oxford University Press, 1932, Cloth, \$1.00.

There is something ennobling and elevating in this little book on the advance of medicine which the medical bibliophile will no doubt cherish. Most of our medical books are dead and forgotten long before their authors have lived their span of years. Not this book.

Moynihan has projected his being into the distant past and has made classical figures in medical history seem like living contemporaries and he has defily welded theo together with our modernists so as to inspire renewed faith in the accomplishments and in the future of medicate

The reader may not quite agree with his unbounded praises for Lister and the utter disregard for Pasteur. Possibly he has here revealed himself as an uncompromising nationalist. This important omission may be pardonable on the basis of one's national pride but will be more than balanced by the superb style and culture reflected in every paragraph.

EMANUEL KRISISY.

COMMUNITY HEALTH ORGANIZATION, A Manual of Administration and Procedure for Cities of 100,000, with Suggested Modifications for Larger and Smaller Urban Units. Edited by Ira V. Hiscock. Octavo of 261 pages. New York, The Commonwealth Fund, 1932. Cloth, \$2.50.

"Community Health Organization" is a new and completely revised edition of the volume published in 1927, is a book of 18 chapters and 251 pages and is published by The Commonwealth Fund under the editorship of The V. Hlscock, Professor of Public Health, Yale School of Medleine. It is sponsored by the Committee on Administrative Practice of the American Public Health Association and reflects that Committee's judgment concerning the scope and content of desirable health services after 12 years study of the health organizations of over 200 communities ranging in population from that of Chicago and New York to towns of 20,000 inhabitants.

The Committee has collected information concerning prevailing administrative health practices, has analyzed this data, has conducted extensive surveys, has recommended special types of organization for communities having special problems and has watched the development of the programs, has developed appraisal forms for city and rural health work, has studied public health records and the relationship of health departments and hospitals and, in short, has exhausted all available sources of information and has apparently spared no effort to make this an authoritative, comprehensive and practical plan of organization for all desirable public health activities.

One would think from the extensive material studied

and digested that this comparatively small volume would be stuffed with tables of statistics interspersed with short explanatory text and would be highly sophorific. This is not so. It conveys a vast amount of information in a highly interesting way and the reviewer eordistly recommends it not only to other public health officials who will need it in their libraries but to his fellow members of the medical profession who will find it most readable and informative.

To illustrate the comprehensiveness of the subject matter treated the chapter of but 17 pages on School Hygieue contains sub-licads on Purposes, Communicable Disease Control, Sanitation of School Buildings, Health Examinations, Professional Attention, Nursing Service, Records, Physical Education, Health Education, The Balaoced Program. Cloldren in Industry, and Personal and Budget. Each branch of public health work is likewise comprehensively treated in all its phases. At the end of each chapter is the Committee's appraisal of the number of full-time and part-time workers with salary schedules needed for that particular health activity in a city of 100,000 people, the unit used by the Committee throughout the book. Everywhere are scattered yardsticks by which the Health Officer can compare the work of his different bureaus with what the Committee consider reasonable standards of public health service.

The only criticism the reviewer would make is that the total per capila cost seems somewhat high and more than most city administrations are willing to incorporate in their budget. However, the editor states: "The plan contains the elements of the best present practice in the country, applicable for one organizing a health department in a community where there is a reasonable mnount of money available. The plan should not be considered as a scheme for immediate adoption as a whole, but for gradual adaptation to existing programs after consider-

gradual adaptation to existing programs after consideration of local problems, possibilities and future policies." The bibliography is most complete and is conveniently placed at the bottom of the pages.

J. F. Morrison,

THE PRACTICAL MEDICINE SERIES. Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Series 1931. Chicago, The Year Book Publishers, 1931. Neurology, Edited by PETER BASSOE, M.D., and Psychiatry. Edited by FRANKLIN G. EOUUGI, M.D. 12mo of 471 pages, illustrated. Cloth, \$2.25.

In this volume, attention is given to a review of the literature for 1931 in the field of Neurology and Psychiatry.

There are interesting articles on cephalic auscultation and epilepsy. The latter is treated from the standpoint of physiology and chemistry with discussion on sodium chloride and water balance, the urea content of the spinal fluid and relationship with tetany as elucidated by calcium and alkali reserve determinations. Several new varities of arachidits, leptomeningitis and encephalitis are described. There is discussion of the etiology of potionyclitis and encephalitis with reference to different types of polio virus. There is also a summation of an article classifying intra-medullary cord tumors.

In the field of psychiatry, there are a series of articles of a general nature dealing with the relation of psychiatry to other branches of medicine, the amount of psychiatry tanght in the medical schools of the country and psychoanalytical technique. There is an interesting article on the use of, inhalation of carbon dioxide and oxygen and intravenous sodium amytal on certain neuropsychiatric conditions. Attention is directed toward the major psychoses, Finally there are a host of articles on mental hygiene and the social psychiatric field. This book should be read by all physicians, as the manifold neurological and psychiatric problems discussed, necessarily border on all fields of medicine.

STANLEY S. LAMM.

OUR NEIGHBORS

DUES AND MEMBERSHIP IN TEXAS

Last year the dues in the State Medical Association of Texas were made eight dollars, instead of ten dollars as formerly. The argument for the reduction was that doctors would thereby be induced to retain their membership in the State Association. Regarding this expectation the Texas State Journal of Medicine for March says:

"On March 1 of last year, our paid membership was 1,275. On the same date this year, our paid membership was 998, a shortage of 277. The figures reported for last year were commented upon at that time, in view of the fact that they showed an increase over the previous year of 127. Deducting this increase from the present shortage, we deduce that we are behind the normal just 150 members. That is now, however, the frank way of looking at it. The truth is, we have recently reduced our dues 20 per cent, which means that our membership should be increased that much if we would compensate. It was following insistence upon this phase of the situation that there was an increase in membership last year, in the face of the depression.

"We are still in need of the 20 per cent increase in membership. Indeed, we are in need of more than that. Our advertising income has been

reduced materially (and more than it should, we are sure), and the cost of doing business has not decreased in proportion. Salaries have been reduced, and printing is a little cheaper, but postage has actually been increased. Most of the items that have been so noticeably reduced in price are not purchased by the association. So it happens, that those of us who are interested in the welfare of the State Medical Association, and of all times in the history of our profession now is the time when we should be interested, should not fail to do two distinct things: (1) Boost the payment of dues; (2) boost our advertising business.

"Some of our advertisers have quit us because the depression has given them an excuse. Some have quit because they are uneasy and desire to hedge financially, while others actually could not afford to continue. No matter, those who are staying with us, and who continue to pay us, are entitled not only to credit, and to our thanks, but to our business as well. They should know that we appreciate that fact. And by the same token, if they are made to realize it, we will hold their business, and many of the lost sheep will return to the fold."

FEATURES OF MINNESOTA ANNUAL MEETING

The February number of *Minnesota Medicine* has the following description of some unusual features of the coming annual meeting of the Minnesota State Medical Association:

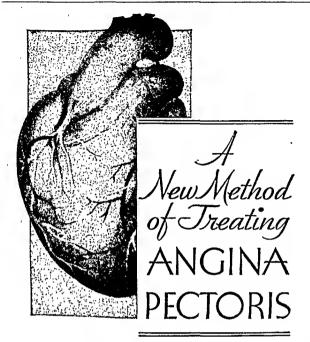

"A call for every available scientific film of interest has been issued by the Committee on Scientific Assembly to all members of the State Association. These films are to be used for the Scientific Cinema which is to be an important feature of the eightieth annual meeting of the society to be held in Rochester, May 22, 23, and 24, 1933. Eighteen films, most of them new, have already been submitted for the committee's consideration.

"A wide variety of small group demonstrations is also under consideration by the committee as another exceedingly important part of the meeting program. These demonstrations, following the precedent set last year at the Saint Paul meeting, will be given for an hour each day in the same halls that house the scientific and technical exhibits. Among the subjects tentatively scheduled for them are many that were suggested by the membership on cards sent out last month by the committee. They include malaria treatment

for syphilis; the Elliot use of heat in pelvic disease; physiotherapy for arthritis; injection treatment for hernia; autopsies; bruises and sprains; practical dietaries; interpretation of blood pictures; psittacosis; the state of vaccine treatment in lobar- and broncho-pneumonia; diagnosis of early pregnancy; pernicious anemia; mucin treatment in peptic ulcer; liver and renal function tests; practical therapy for allergic states; oxygen therapy; fractures; hemorrhoids; spinal anesthesia; diathermy vs. surgery for tonsillectomies; plastic surgery; intravenous technic in leg ulcer; deformities after wrist fractures; tularemia; relation of streptococci to the etiology of ulcer; experimentally produced peptic ulcer; studies of gastric secretion; symptoms of hematemesis; lesions of the stomach; retinal hypertension; cancer of the uterine cervix; intravenous urography; ketogenic diet in urinary infections; technic of making and staining blood smears; differential characteristics of malignant cells; phtelometer and electromotive thermometer.

"Prominent among other novel program fea-

(Continued on page 480-adv. xii)

N the treatment of angina pectoris, vasodilators, especially the

nitrates, have proved helpful in relieving acute attacks, but they exert only a limited influence upon the course of the disease.

Because of its prolonged action upon the coronary arteries, Myorgal, a preparation of active nucleosides, prevents the acute attacks and exerts a beneficial influence by improving the nutrition of the heart muscle.

Anumber of reports have been published attesting the value of Myorgal in various types of angina pectoris. It has also proved of decided benefit even in the presence of cardiac dilatation and decompensation when administered with digitalis.

OTHER INDICATIONS: Myorgal has also been recommended in the treatment of cardiac neuroses in general, sclerosis of the cerebral vessels, and the vascular disorders of the menopause when associated with anginal manifestations.

Literature on the action and therapeutic indications of Myorgal will be sent to physicians on request.

DOSE: One tablet, two or three times daily, increased if necessary.

MYORGAL

Pronounced My'-or-gal formerly LACARNOL

WINTHROP CHEMICAL COMPANY, Inc.

The New York Physicians' Mutual Aid Association

In 1868 a group of physicians in New York State organized and incorporated The New York Physicians' Mutual Aid Association, to have for its objects:

- (a) To pay death benefits to the estates of deceased members or to designated beneficiaries, and
- (b) To furnish pecuniary aid to members in cases of urgent need.

The founders builded better than they knew, for from their small beginning of less than a hundred members there has grown an Association whose membership now is in the thousands.

This Association makes no distinction as to sex, race, creed, or color, welcoming all that are eligible to its membership at the actual cost of the service it performs. Its officers and trustees receive no salaries or other financial recompense, feeling honored in being chosen by their colleagues to manage its affairs. They are elected each year at the annual meeting of the Association. Full information may be had from the headquarters of the Association, New York Academy of Medicine, 2 East 103rd Street, New York City.

THE ANNUAL MEETING

of the

Medical Society
of the
State of New York

will be held at the

WALDORF-ASTORIA NEW YORK CITY

April 3rd, 4th, 5th, 1933

(Continued from page 478)

tures are the meetings of the special societies to be held Monday. These meetings will provide open programs on surgery, dermatology, obstetrics, heart tuberculosis (arranged by the Trudeau society), orthopedics. eye and ear and

r-ray.

"Several symposiums of special interest are being arranged for the Tuesday and Wednesday programs. One of these is to be a nutritional symposium and another emergency surgery, with a pathological conference and a cancer symposium also under consideration. Subjects of papers to be read include pneumonia, gastric ulcer therapy, migrane, epilepsy, management of hypertension, management of cancer, asthma in infants and young adults, diabetic management in general practice, prevention of obstetrical castastrophes, industrial surgery with estimation of disabilities.

"Clinics to be held in Rochester hospitals will occupy Tuesday and Wednesday afternoons. The usual social events, gold tournaments, luncheon reunions and banquet, together with various special tours, will complete the unusual three days' program.

INSURANCE PLANS IN WEST

The March issue of the West Virginia Medical Journal has the following editorial on the solicitation of applicants for the insurance of hospital care:

"From time to time the attention of the Association is called to some new form of health insurance in West Virginia that involves the solicitation of patients. Every doctor and every hospital that subscribes or participates in any plan of health insurance should first make sure that the element of solicitation is entirely eliminated. Solicitation of patients is the one thing that will bring havoc to the medical profession, because it creates dissension and strife within the profession itself. Organized medicine has little to fear so long as the doctors put up a united front, but organized medicine has everything to fear if the doctors lose faith in one another.

"Somehow it rarely occurs to the average doctor or hospital superintendent that there is one form of solicitation that is entirely harmless, that is, the solicitation of patients for some form of health insurance that leaves the patient absolutely free to select the doctor and the hospital of whis choice. One such plan is already in operation in West Virginia and, while it has certain faults, it does not antagonize the doctors with the solicitation problem.

"No group of doctors and no group of hospitals can operate any ethical plan of health insurance unless all the doctors and all the hospitals are in-

(Continued on page 481-adv. xiii)

(Continued from page 480-adv. xii)

luded in the plan. That should be he iron-elad ule in every health insurance plan. Otherwise, ither the plan or the profession will sooner or

ater come to grief.

"Suppose in a community there is a real leader of the profession. He looks far enough ahead to nticipate the chaos that will result from the plan nutlined above. So he gets the two hospitals together, he explains the whole matter to the staff nembers of both hospitals, he recognizes the denaud for some monthly-payment plan, and the wo hospitals join hands to work out their mutual problem. The result is a plan that may employ the same solicitor at the same rate, but which gives all subscribers free choice of hospital and physician. Here, instead of chaos, we have union. We have a plan that will draw the hospitals and the physicians together, instead of driving them further apart.

"The journal does not for one minute advocate the organization of health insurance plaus throughout the state, nor does it endorse any particular plan in any particular community. We do feel that in some sections, where there is an unquestionable demand for some health insurance plan, the doctors and the hospitals would be wise to go into the matter openly and frankly and work out a satisfactory solution before someone else works out an unsatisfactory plan. There is no reason why any county society should hold aloof

from such a move."

GRADUATE COURSES IN VIRGINIA

The February issue of the Virginia Medical Monthly contains the following description of the courses in Prenatal Care:

"The third circuit of five post-graduate classes conducted by Dr. Maxwell E. Lapham, of Philadelphia, full-time clinician of the Joint Committee on Prenatal and Postnatal Instruction, came to a close in the last week of January. These classes were located in Roanoke and adjacent cities. One new enrollment during the month, that of Dr. G. A. L. Kolmer, brought the membership for the circuit to a total of fifty-two. The attendance for the first part of the course was somewhat better than the records of previous circuits; and it remained creditable to the end, in spite of the disadvantages of the holiday intermission, rough weather, and the busyness of the season.

"As in previous classes, every enrolled member was invited to give the Joint Committee the benefit of his frank opinion as to the value of the course and his suggestion for further improvement. The replies received at the time of writing have been unanimous, with a single exception, in stating that the course was worth the cost in time and money—twenty-three affirmative to one opposed; and that similar courses in other subjects would be welcomed—twenty five affirmative to none opposed. (Continued from page 481-adv. xiii)

"In its first nine months the Joint Committee has now completed sixteen classes with a total enrollment of 228. Of this number only six have been doubtful of the value of the work, and only six have indicated their lack of interest.

"The fourth circuit of classes in and around Norfolk, as described below, and an intensive course of two weeks already arranged for Bedford in April, will end the year's work. The organization of additional study groups for the summer in the most distant sections of the State will be immediately undertaken.

"Unanimous votes in approval of the courses in prenatal and postnatal care by the medical societies of Norfolk, Nansemond and Southampton Counties, and the application of members of the (colored) Norfolk-Portsmouth Medical, Dental and Pharmaceutical Society, have resulted in a more favorable beginning for the fourth circuit than in any previous groups of classes. Active committees on membership and clinical material and an advance enrollment of fifty-one are indications of the success that may be confidently expected in the graduate courses conducted in the new territory."

PSYCHIATRIC NEEDS OF WEST VIRGINIA

The February issue of the West Virginia Medical Journal records a controversy between the Governor of the State and the medical profession over the State Hospitals for the care of the Insane. The Governor seems to have accused the doctors of selfishness when they criticize the hospitals. Dr. D. A. MacGregor, President of the State Society, reviews conditions in the hospitals on the President's Page of the Journal as follows:

"Our state provides four hospitals for the care

of mental diseases. As custodial institutions they afford quite comfortable and satisfactory accommodations for about 3,300 patients. At the present time this capacity is slightly inadequate, but the problem of over-crowding is not serious.

"During the past two years there have been several important additions to the physical equipment of these institutions. Provision has been made for x-ray study, clinical laboratory examina-

ization, and all decisions as to the formation and conduction of clinics, the time, place and method of operation, as well us the selection of clinicians, is a matter to be settled entirely by the local Society. Several County Societies in Illinois, are now organizing their own clinic, to be conducted entirely by their own members, while several others have requested that the Scientific Service Committee aid them in selecting an outside clinician for the actual work.

"In adopting this outline schedule form as recommended by the Council, no additional expense is incurred by the Illinois State Medical Society, there are no field workers, organizers, traveling representatives, or other paid executives working at the expense of the Society, but the Society is merely using an office already ereated which is ever anxious to be in closer communication with all component County Societies, and assist them in every way possible.

"It is recommended in the outline that all patients able to do so, should pay a reasonable fee for services rendered, to reduce to the minimum, unnecessary pauperization, although, of course. final decision in this, as well as all other questions relative to the operation of clinics, is a matter to be decided by the County Society itself.

"It has been shown repeatedly, that in many of our communities there are physically handicapped children who have not actually been seen by the family physician since delivery, or after postnatal care was discontinued, and many of these cases have been discovered and brought to the Clinics by Welfare Nurses, or other workers, which again shows the value of these cooperative individuals or organizations in the clinical program.

'All decisions relative to the creation of physically handicapped children's clinics, are in the hands of the County Medical Societies, and if any additional information is desired relative to any phase of the subject, same will receive prompt attention, by addressing Miss Jean McArthu, Secretary, Educational Committee, Illinois State Medical Society, 185 North Wabash Avenue, Chicago,"

The Journal also gives the following description of a elinic held in Warren County:

"The regular Physically Handicapped Children's Clinic conducted by the Warren County Medical Society was held at the Monmouth Hospital, on January 19, 1933. This clinic established by the Society six years ago, has been gradually increasing in popularity, and has shown conclusively, that County Medical Societies can success-

fully conduct their own clinics without question. The citizens of the Community have not only been intensely interested with its progress, but have given many types of encouragement. The Society has had the cooperation of a group of women who formerly were interested in this type of welfare work, and who are now furnishing the necessary operating expense money,—a highly essential factor. The Press has always been generous in their reports and publicity for each clinic that has been held.

"During the clinic, a stenographer is present to take notes from which the records are properly revised and brought up-to-date subsequently, and as an additional check-up, a dictaphone is also used so there will be no question as to the findings, and prescribed treatment for the case. When x-ray pictures are desired, they are made immediately, and reported to the clinician before the patient leaves the hospital. Most of these bills are paid immediately by the patient, but in the case of those who are unable to pay for this service, the obligation is assumed by the special ladies' committee which is always in attendance.

"At the clinic on January 19, a total of fortyone patients were seen; twenty-seven of these had been seen previously and fourteen were new patints at the clinic for the first time. The family physician was present during the day, in nearly every instance, and he received definite information relative to his patient from the clinician.

During the six years this clinic has been in progress, it has been a matter of unusual interest to the physicians in attendance to see the wide range of orthopedic conditions presented for observation, and subsequently, to note the satisfactory progress of nearly every case. Some patients seen at early clinics, when they were carried in the arms of parents, are now seen walking satisfactorily. A number of endocrine disturbances diagnosed one or two years ago show a decided improvement under the prescribed treatment, as is noted particularly on x-ray examination."

WOMAN'S AUXILIARY IN ILLINOIS

The report of Mrs. T. O. Freeman. President of the Woman's Auxiliary of the Illinois State Medical Society, is printed in the March number of the Illinois Medical Journal, in which the following items appear:

"The President of the State Medical Society and Secretary of the Educational Committee advised that the Illinois Medical Society had endorsed 'Hygeia,' and the Board decided to ask the County Auxiliaries to take up promotion of 'Hygeia.' A special committee was named for 'Hygeia,' with Mrs. G. E. Johnson, Chicago, as Chairman.

"The Publicity Chairman was requested to col-

(Continued on page 487-adv. xix)

lect clippings on matters of interest to the Auxiliary, to be made into scrap book for future reference. This scrap book was part of an exhibit at the National Convention in New Orleans.

"A letter was sent to Dr. Andy Hall, Commissioner of Public Health for State of Illinois, assuring him of our support in his work for compulsory vaccination, and offering to assist him in any way possible. Dr. Hall replied stating he

appreciated our offer of eo-operation.

"Plans for study programs were discussed and it was decided to continue with programs suggested by the Educational Committee of the Illinois State Medical Society for the previous year. The following subjects were made the basis for programs for this year:

"Contagious Disease Control and Emphasis on

Smallpox.

"Legislation—Medical Practice Act, Bills, etc.
"Survey of Magazines with regard to their presentation of Medical Practices, costs, etc.

"A Thorough Study of the Magazine 'Hygeia.'
"List of Books written by Doctors or about Doctors with review of several.

"Some Economic Aspects of the Practice of

Medicine.

"Child Welfarc and the Examination of School

Children.

"In April a letter was addressed to County Presidents calling attention to an article in a popular magazine, and the comment on this article which appeared in the April Illinois Medical Journal. Presidents were asked to bring this before their auxiliary members requesting each one to pledge herself to interest three lay friends to write letters of protest to this magazine.

"Up to date we have eleven active organized counties, with 555 paid members, as follows:

"Wills Grundy County, 25; St. Claire County, 57; McLean County, 13; Randolph County, 15; Cook County, 298; Vermilion County, 52; Kane County, 21; Rock Island County, 18; Douglas County, 10; Coles Cumberland County, 12; Sangamon County, 35."

ANNUAL MEETING IN ILLINOIS

The March number of the Illinois Medical Journal contains the following editorial description of the Annual Meeting of the State Medical Society to be held in Peoria, May 16-18, 1933:

"The meeting will begin on Tuesday morning, May 16th, with the Annual Secretaries' Conference, which will begin at 10:00 o'clock. The officers of the Conference are arranging an unusually interesting program that will appeal not only to the officers of the component societies, but to other members as well. It is hoped that the attendance at this conference will exceed that of former years.

"The General Opening Meeting which has previously been held on Tuesday evening, has been changed to 1:00 P.M. when the President will officially call the meeting to order. This session will be very brief, and will be followed by the Oration in Medicine. All Sections will be in session that afternoon from 3:00 to 6:00. Tuesday evening from 6:00 to 8:30, will be given over to the Veterans Dinner, for which the Committee is arranging an excellent program, the Fraternity, Alumni, and Section Dinners, as desired. At 8:30 that evening, the Peoria Society will be host at the Annual Stag, and this will be entirely different from the usual entertainment of former years.

"All Sections will Wednesday morning from 8:30 to 11:00, and from 11:00 to 12:00 the Oration in Surgery will be given. The President's Address will be given at 1:30 P.M. Wednesday,

to be followed by Section meetings.

Wednesday evening is to be used to honor our President, Dr. John R. Neal. The President's Dinner will be held at 6:30, and there will be no speeches during or following the Dinner. The President's informal dance, or cards, as desired, will follow, and occupy the remainder of the

evening.

"On Thursday morning, the five Scientific Sections will join together for a meeting which will interest all members, regardless of their specialty in practice. Forty minutes is available for each Section to present interesting subjects, and there will be time for discussion of all papers. It is quite probable that two or three of the Sections will arrange a symposium taking up the various phases of some interesting group of conditions, complete details will be announced in the April Illinois Medical Journal.

"The House of Delegates will have the first meeting at 3:00 P.M. Tuesday, to hear the annual reports of officers, councilors, committees, the presentation of resolutions, and other business which will be presented for action by the House.

"The second meeting of the House of Delegates will be held at 8:30 Thursday morning.

"All exhibits, both commercial and scientific, will be shown in the Pere Marquette Hotel, and arrangements are under way to have an excellent display which will be of interest to everyone at the meeting."

HOUSE OF DELEGATES IN FLORIDA

An editorial in the February Journal of the Florida Medical Association, Inc., describes one of the customs of the House of Delegates which seems strange to New York physicians:

"We are now selecting men who will represent us in the house of delegates at our annual meeting to be held in Hollywood in May. In this house

(Continued on page 489-adv. xxi)

(Continued from page 488-adv. xx)

last year a precedent was set in that a person desiring to address the house, if he were not a properly seated delegate, had to obtain permission from the hody. If this method of procedure is to continue-hand we believe it should—much valuable time could be saved, if individuals, who are qualified to speak with authority, should be elected as delegates and to those individuals should be handed, for introduction, any matter which a component society wished brought up, thus discouraging extra corporal speaking. Thus, the ruling body of the society, is always rushed for time, and overcharged with work, so every moment that

it is in session should be conserved and not wasted by this injection of unseated speakers, and of oratory, often of a meaningless type, on some subject which a regularly elected delegate could and should have introduced.

"It might even be well to have the house of delegates meet only in executive session. Then each county would be desirous of sending as a delegate only its strongest and best informed men—men who could and would truly represent, and not men who meaninglessly waste not only their own time like our curbstone friend, but also the time of others, which tests the temper, even of angels."

INDIGENTS IN DELAWARE

The February number of the Delaware State Medical Journal has the following editorial description of medical relief work among the indigents of the State:—

"Success has at last been achieved by the organized medical profession of the state in its efforts to be relieved of part of the burden of caring for the indigent sick in their homes. Following a conference between officers of the State and County Medical Societies and officials of the State Temporary Emergency Relief Commission a plan

was evolved under which the two most important objectives of the profession have been recognized; (1) the patient shall have free choice of physician; and (2) the physician shall receive some remuneration.

"The plan works as follows: when an indigent needs medical attention he makes application to the nearest Relief Commission office, of which several will be established throughout the State. His indigency will then be investigated by the

(Continued on page 490-adv. xxii)

(Continued from page 489-adv. xxi)

Commission, and if verified, the Commission will then ascertain the name of the physician chosen by the patient, and request the physician to treat the patient.

"If the patient is not able to make application to the Commission in person, application can be made by any member of the family, or by any friend or neighbor, after which the wheels will start moving as above. Where the doctor is needed promptly or at once, he is to be called first, and the Commission then notified of the case.

"The physician shall keep the usual record of his visits and treatments, medicaments, and supplies, and, on the discharge of the patient, shall render his bill for this service to the Commission office that issued the original authorization. Upon verification of the account, the bill will be paid out of the Relief Commission's funds. amounts agreed upon at present are: for the first visit, 50 cents; for subsequent visits, 35 cents; for dressings and materials, 25 to 35 cents; for drugs dispensed, 35 to 50 cents. These sums are not considered fees; they are to be booked and billed as part of the physician's expenses in attending indigent cases. Cases treated in the doctor's office or in some organized clinic do not come within the purview of this agreement, as it stands at present.

"The promptness with which the Commission officials agreed to this plan is a matter for congratulations, both to them and to us. Their fairness in conceding at once that the whole burden of providing medical care for Delaware's indigent should not rest solely on the medical man's back is a guarantee that this fundamentally important Commission is composed of men of broad vision. They do not hesitate to acknowledge that the charity contributed by the Delaware medical profession, estimated at \$2,500,000 a year, is the most persistent and the most consistent charity in the state.

"Furthermore, their willingness to help lighten this load shows that, after all, the intelligent layman can and will understand some of the medical man's problems if only they be placed clearly before the laymen; which is equivalent to saying, conversely, that one reason why the doctor now finds himself in serious straits is because, with his inherited and acquired timidity over direct approaches to the public, he has not taken this same public into his confidence enough for Mr. John J. Businessman to realize that medicine means much work, little pay, and many problems which the doctor alone cannot solve. Whether we doctors like it or not, our public relations and the means thereto are changing. We, too, had better change our tempo and keep step with the times."

CHIROPRACTIC IN TEXAS

The first article in the March issue of the Texas State Journol of Medicine describes a chiropractic bill which was introduced in the House on February 10, and a motion to refer it to the Health Committee was lost by a vote of 64 to 55. The account continues:

"Immediately following the announcement of this vote, and presumably as a joke, a motion was made to refer the bill to the Committee on Live Stock and Stock Raising. This motion carried, and the bill was so referred.

"A hearing on this measure was conducted by the Committee on Live Stock aud Stock Raising. February 16, in the main hall of the House of Representatives. A large audience was present, and for the first time that we can reall, the opponents and proponents of the chiropractic bill were about equal as to numbers, and for the first time in the history, we think, the chiropractors failed to conduct a clinic.

"Dr. Marvin D. Bailey, as osteopathic physician from Houston, representing the State Board of Medical Examiners, was chairman of the opposition and directed the fight on the bill. Judge B. Y. Cummings, of Wichita Falls, delivered the principal argument against the bill. Dr. N. D. Buie. of Marlin, president, represented the Board of Medical Examiners; Mrs. Bertha C. Alford, chairman of their legislative committee, represented the Graduate Nurses Association; Dr. H. C. Morrow of Austin, represented the Homeopaths and Eclectics; Dr. Paul M. Peck, of San Antonio, represented the Osteopathic group, and Dr. Holman Taylor, of Fort Worth, represented the State Medical Association of Texas.

"At the conclusion of the argument Representative Jones moved that the bill be referred to the House with the recommendation that it do not pass. This motion was defeated by a vote of 6 to 7.

"The committee met again on February 22 and reported the bill unfavorably, by a vote, we understand, of 8 to 9."

Diuresis is recommended in many forms of Heart Disease as an adjunct to other appropriate treatment.

LECTURES TO MEDICAL STUDENTS IN INDIANA

The February Journal of the Indiona State Medical Association has the following account of a course of lectures to senior medical students, which is much more extensive than that given under the auspices of the Medical Society of the State of New York:

"The Indiana University School of Medicine has announced a new course in medical economics and medical ethics to be given to the senior class. This course has been approved by the Indiana State Medical Association. Members of the Indiana State Medical Association are invited to attend the lectures, which will be as follows:

"1. General Principles of Ethics—Mr. Daniel S. Robinson, Dept. of Philosophy, Indiana Uni-

versity,

"2. Principles of Medical Ethies –Dr. J. M. Barry.

"3. Work and Ideals of Organized Medicine—Dr. Joseph Weinstein.

"4. Newer Forms of Medical Practice—Dr. Olin West, Chicago.
"5. Duties of the Doctors in Safeguarding Public Health—Dr. Thurman B. Rice.

"6. Conduct of Consultations-Dr. William N. Wishard, Sr.

"7. Prognosis — Dr. J. Oscar Ritchey.

"8. Code of Medical Ethics— Dr. W. D. Gatch.

"9. Problems of the Young Physicians—Dr. Cyrus Clark.

"10. Savings and Safe Investment—Mr. Evans Woolen, Jr.

"11. The Mathematics of Life Insurance—Mr. Charles Beckett. "12. Life Insurance Examina-

tions—Speaker to be announced.
"13. The Office Equipment of the Doctor—Dr. Carl McCaskey.

"14. The Work of the Indiana State Board of Medical Registration and Examination—Dr. William R. Davidson.

"This course of lectures will begin at 1:00 o'clock on Wednesday, February 1, and thereafter the classes will meet regularly each week on Wednesday at 1:00 o'clock.

April 15, 1933

THE MEDICAL SOCIETY OF THE STATE OF NEW YORK: OUR RESPONSI-BILITIES AND OUR OBLIGATIONS

By CHAS. GORDON HEYD, M.D., NEW YORK, N. Y.

The Presidential address at the 127th Annual Meeting of the Medical Society of the State of New York at the Waldorf-Astoria Hotel, New York, Tuesday, April 4th, 1933.

THE Medical Society of the State of New York has 13,400 members, in sixty component County Medical Societies, and represents in its membership a single, consolidated, medical organization working in harmonious relationship from one end of the State to the other. It would seem wise therefore to canvass a few of the salient backgrounds of the practice of medicine, and to see wherein the Society has fulfilled its obligations.

THE INDIVIDUAL PRACTITIONER

The fundamental object of medical practice is to provide and make available adequate, effective medical service; and the most effective basic unit for the distribution of this service is the individual practitioner of medicine. We believe that medical service today in the State of New York is both effective and efficient, though in some localities it is not readily available, and rarely is inadequate!

If the practice of medicine from the community viewpoint was ineffective or inadequate, we should expect that society in the United States would suffer from such defects of medical service. This is not apparent because the decline in modern mortality is impressive. If the death rate which obtained in 1900 had continued unabated, there would have died in 1925 approximately 1,962,999 people; on the contrary, the actual deaths were 1,389,673 persons, an actual saving of life in the year 1925 of 573,326 lives.² Paralleling this gross mortality decline has been a reduction in the per thousand per annum death rate from 18,6 to 9.6.

BURDEN OF FREE SERVICE

There is no logical reason for believing that the professional item for adequate and effective medical care will be materially lessened or reduced, for any plan to meet the so-called inadequacies of medical service will certainly carry with it a remuneration to the physicians for the professional services rendered in clinics. Since the doctor is a citizen and must discharge all of his obligations of citizenship the same as other individuals in the community, he is by the same token entitled to a monetary return for his labor, experience, and knowledge that is commensurate with the services rendered and with his training and experience.

The present day method whereby the tyranny of hospitol and dispensary administration enforces free services from their attending staff is ethically wrong and economically unsound.

The doctor must be paid for his services irrespective as to the method of distribution in order that he, as an individual, may function as a useful and contributing member of society.

In 1900 there were 160 medical schools in the United States, and today there are 66. Yet, we are producing approximately the same number of physicians today from 66 schools as we did in 1900 from 160. Whereas the population in the United States increased from 1890 to 1930, 95 per cent, the number of graduates from institutions of higher learning increased over 1,360 per cent.

Before 1929 fifty per cent of the physicians in this country had an annual gross income of \$3,800 or less; and 25 per cent of the total number of physicians had an annual gross income of \$2,300 or less.⁴ This is in remarkable contrast to the fact that in the same period a conductor of a railroad freight train received about \$3,750 a year and a locomotive engineer about \$4,700; while the very meagre budget of a street railway employee of about \$1,900 a year* was only \$400 a year less than that received by 25 per cent of the physicians after an extensive and prolonged, costly and special type of education. It may be said without fear of contradiction that there can be no solution of medical costs by a reduction in the average professional medical income.

It is axiamatic that whenever the remuneration for professional services becomes meager or difficult, there is a fundamental lessening in the

FOR THE TREATMENT OF CHRONIC ARTHRITIS

Many clinicians hold to the theory that arthritis is due to a streptococcic infection. Subcutaneous injections of streptococcus vaccines, both autogenous and stock, have been used for many years with indifferent results in the treatment of arthritis.

A strain of Streptococcus viridans that has been under cultivation, for nine years or more, is of low virulence and safe for intravenous injection, is now available and is in growing use in the treatment of chronic arthritis. This new biological is a product of the Lilly Laboratories. The basis upon which its use is advocated rests upon the work of Drs. Clawson and Wetherby, of Minneapolis, Minnesota, and the results they obtain in administering a streptococcus vaccine, intravenously, in over five hundred patients.

Streptococcus Vaccine (Intravenous), Lilly, is not the ordinary streptococcus vaccine. It is a monovalent vaccine prepared from a strain of Streptococcus viridaus isolated from a case of acute rheumatic fever. It is available in 20 cc. rubber-stoppered vials. A booklet will be sent upon request addressed to Eli Lilly and Company, Indianapolis, Indiana.—Adv.

VITAMIN "D"

Winter is a jailer who shuts us all in from the fullest vitamin D value of sunlight. The baby becomes virtually a prisoner, in several senses: First of all, meterologic observations prove that winter sunshine in most sections of the country averages 10 to 50 per cent less than summer sunshine. Secondly, the quality of the available sunshine is inferior due to the greater distance of the sun from the earth altering the angle of the sun's rays. Again. the hour of the day has an important bearing: At 8:30 A. M. there is an average loss of over 31%, and at 3:30 P. M., over 21%.

While neither Mead's Viosterol in Oil 250 D nor Mead's 10 D Cod Liver Oil with Viosterol constitutes a substitute for sunshine, they do offer ar effective, controllable supplement especially important because the only natural foodstuff that contains appreciable quantities of vitamin D is egg-yolk. Unlike winter sunshine, the vitamin D value of Mead's antirachitic products does not vary from day to day or from hour to hour.—Adv.

VICHY CELESTINS

The American Agency of French Vichy, Inc., sole American agents of

"Vichy Célestins" water bottled at the Spring at Vichy, France, owned by the French Government. There are other Springs at Vichy also owned by the French Government such as Grande Grille and Hopital which are imported by these Agents but these are not sent here in as large quantities as the "Vichy Célestins." This Agency also importe the tins." This Agency also imports the Vichy Salts and Vichy Pastilles which are called Products of Vichy-Etat because they are made from the Salts extracted from the waters of these government-owned Springs. Medical Profession of the United States annually sends many patients for the treatment of diseases of the stomaclı, liver, etc.-Adv.

PNEUMONIA

The most recent statistics dealing with pneumonia indicates its successful control in a large number of cases. In 707 cases of pneumonia in which Type I Antipneumococcic Serum was used, the death rate was 18.5% as compared with the untreated cases, in which the death rate was 30% in 553 cases. When serum was used within 72 hours after the onset, the death rate was 10.7% in 177 cases.

Its refinement, as well as its standardization in units, gives the physician adequate information, so that the dosage can be correctly estimated from the results achieved.

Full information will be supplied by the LEDERLE LABORATORIES. and communications may be addressed to them at 511 Fifth Avenue, New York City.-Adv.

(5) That no substantial evidence can be produced that, even under an idealistic system of medical service, irrespective of cost, medical service can be provided for all the people, at all times, under all conditions. To accept the thesis that medical service can be so provided is to deny the lessons of experience, and to cancel entirely the human factor—that a great many people in close proximity to adequate medical service never avail themselves of the opportunity.

HOSPITALS

In surveying the medical scene we find the following conditions: the tremendous over-development and over-extension of hospital facilities; the erection of hospital structures and hospital administration that are beyond the capacity of the community to pay for; and in the absence of large donations from extraordinarily rich individuals or foundations, there is little prospect that most of the hospitals can sustain the load that they have undertaken. We find in thirty years a constant diminution in the ward bed service of our hospitals, and a tremendous augmentation in the environmental conditions of comfort and luxury in semi-private and private accommodations.

In 1906, 28 per cent of the hospital beds were classified as ward; 10 per cent of the hospital beds

were classified as semi-private.

In 1928, 7 per cent of the hospital beds were classified as ward; 23 per cent of the hospital beds

were classified as semi-private.

This is a loss of one per cent a year in ward beds. The inference that must be drawn is that the increase in the number of semi-private bedrooms has brought about an increase in the unit cost of medical service.

The number of clinies in the United States in 1930 was over six thousand, in contrast with only about one hundred and fifty in 1900. We find that the clinics in New York City are increasing their attendance at the rate of 200,000 per year; and that at the present time about one-third of the population are attending clinics and dispensaries. An extrapolation of this curve of clinic attendance will demonstrate that the medical needs of the citizens of our large cities will be supplied entirely by clinics and dispensaries.

We find in 1932 that out of 100,000 in-patients in the City Hospitals of New York less than 1,000 contributed anything for their hospital maintenance or medical services. We find the clinics clarging from ten cents to a dollar for admission; and from then on there is levelled against that individual varying charges for all the laboratory tests that may be necessary. These charges vary up to as much as five dollars for a basal metabolism on a so-called indigent patient, so that our clinics in spirit, and in many cases in fact,

are practicing medicine. We are convinced that from 80 to 85 per cent of the illnesses of which mankind complains are simple conditions that can be easily diagnosticated and treated. We are likewise of the opinion that extensive laboratory work should be devoted only to the 15 or 20 per cent of abstruse conditions.

A PLAN FOR MEDICAL SERVICE TO THE POOR IN NEW YORK

We find yearly a tremendous number of individuals exceptionally trained and unusually well educated seeking admission to the medical profession, a field of professional activity that has apparently readied the saturation point as it is showing an annual accretion in numbers of 1,600 more graduates than deaths in the profession, with the number of doctors throughout the United States distributed in rather remarkable proportions, one physician to 1,431 of the population in South Carolina, one to 571 in California, and one to 621 in New York State.3 It would seem therefore that in a State as well organized as that of New York the worthy poor should obtain all medical services absolutely free of charge; and that in order that these services may be rendered to those that deserve it and to prevent exploitation and a fraud against the taxpayers, such worthy poor should be registered and have a certificate of indigency, and should be directed to a hospital that could serve their needs in the geographical area of the community in which they reside.

For this service to the poor the hospital should be remunerated from the general tax funds; and the doctors providing the professional services within the institution or clinic should be paid a fair and reasonable compensation. To all other patients not coming within the classification of indigency a service charge should be made in keeping with their economic resources.

The funds derived from the tax rate for the maintenance of this service to the poor should not be allocated by the hospital authorities to the general expenses of the hospital, but should be used for maintaining the equipment and the physical condition of the clinic, as well as for the compensation of physicians for their professional services. These two features would imply an unequivocal enforcement of the dispensary law. The benefits that would accrue from such a policy would be to bring free clinic and hospital services within well defined limits. There should be no profit-making element in hospital administration; hence hospital authorities could plan their budgets to serve the community in the best possible way with the least expense consistent with good service. This would lessen hospital deficits by definitely limiting the conditions of free service, and would tend to introduce effectiveness and economy in hospital and dispensary administration.

character of the individuals entering that profession, with a tremendous depreciation in the quality of the service rendered.

We have in this State no lack of medical resources. We have to some extent a defective distribution of medical services; and the greatest problem before the medical profession is to make these services available to the entire population. This will not come about through shackling of society by a colossal incubus of a medical bureaucracy capitalized by the State. We must ask ourselves the question, can society afford all of the panaceas that are recommended to us by professional reformers, non-medical idealists, social service workers, medical technicians, and social theorists in general?

The cost of social service, exclusive of education, represents one-fifth or more of the total expense of our cities, and in the State of Massachusetts the cost is nearly two-thirds of all of the State outlay.⁶

Cost of Federal Government per capita Cost of State Government per capita Cost of City Government per capita	3.97	1929 \$32,26 16.38 58.64
•	\$30.24	\$107.28

The per capita cost of all government has increased as follows:

1890		\$ 13.56
1903		19.38
1913		30.24
1923		88.94
1929		107.28
1932	(it will be approx	imately) 124.00

The present is the time in which everything that is suggested for the betterment of the community should be weighed. It is certainly not the time to enter upon any fanciful excursions into a theoretic state of social benefits. The members of the medical profession stand ready at all times and under all conditions to contribute in full measure their services for the benefit of the community. They have a right to expect that the community shall not exploit them under any State-endowed scheme of "social insurance" the cost of which must be superimposed upon a tax rate that has already reached staggering proportions. The medical profession should be on guard lest, as Benjamin Franklin said, "they pay too much for somebody else's whistle."

It is claimed by competent statisticians that in 1928 physicians treated one-eighth of the population of the United States free of charge. At all times there are two per cent of the population incapacitated, and about four per cent physically impaired. In other words, there are approximately three to four million individuals in the United States ill every day. It follows logically therefore that from 375,000 to 500,000 persons are treated daily without charge—which repre-

sents a money contribution to the community for free medical service week days and Sundays, holidays and work days, of \$750,000 to \$1,000,000, or \$365,000,000 a year. It would require \$7,300,000,000 invested at five per cent to produce this large sum contributed annually by the medical profession.¹

On the authority of Dr. S. S. Goldwater, who certainly may be credited with due caution, it is asserted that this item of professional services rendered by the staff to a hospital exceeds the total of all other contributions received for the year by the hospital. It is pertinent to inquire as to why hospitals charging for dispensary visits and for the services rendered, have so significantly failed in balancing their budgets.

If all the medical and quasi-medical foundations were consolidated into one organization, their entire contribution to society in dollars during the last twenty years is not equal to the annual donation of the physicians of the country. The medical profession may justly claim that, under the present medico-social system, they stand without a rival in the entire field of medical charity

and health philanthropy.

Our studies indicate that there is a very definite increase in the percentage of our population who avail themselves of the dispensary facilities of our so-called free hospitals. It is conservatively estimated that fully fifty per cent of these individuals are not in the indigent or pauper class. but that they pay substantial rents and are in the main self-supporting citizens; yet by availing themselves of the facilities of charitable hospital and dispensary services they are in fact and in principle committing a fraud upon the remaining taxpayers who do not avail themselves of these loopholes of medical charity. It has been repeatedly demonstrated that many patients occupying hospital beds are quite able to pay for their support and maintenance in the hospital, and that by occupying hospital beds they are depriving many of the indigent and worthy poor of hospital facili-The taxpayers' money is being expended for the care of people who are not, in fact, indigent.'8

INDIVIDUALITY IN MEDICAL SERVICE

We believe in the following principles:

(1) That sicknes is the problem of the individual;

(2) That the most desired objective is a continuous improvement of the quality of medical

(3) That future efforts in preventive medicine is an individual problem and one not capable of being solved by the mass efforts of health departments;

(4) That no plan of medical service can be devised that is applicable to the diverse conditions of, let us say, New York City, the rural commu-

THE CONTROL OF MEDICAL ACTIVITIES BY THE MEDICAL PROFESSION By FREDERICK H. FLAHERTY, M.D., SYRACUSE, N. Y.

The inaugural address of the President of the Medical Society of the State of New York, delivered on April 4, 1933, before the House of Delegates, in the Hotel Waldorf-Astoria, New York City.

NE hundred twenty-seven years ago, April 4th, 1806, the New York State Legislature passed an act incorporating the Medical Society of the State of New York. In the original by-laws, written in 1807, it reads "and be it further ordained by the authority aforesaid that the President of the said Society shall at the Annual Meeting and at the end of each year after his election to office deliver to the Society a dissertation on some appropriate subject and in case of default he shall forfeit and pay to the Society a fine of twenty-five dol-This usual address, so far as I can learn, has existed ever since that early date.

Members of the House of Delegates, by virtue of the power invested in your body by the Medical Society of the State of New York, you have seen fit to honor me as your President for the ensuing year. I take this opportunity to thank you for this great honor.

When I review briefly the history of this Society, it fills me with pride to know that I do belong to such an organization, that I am allowed to take part in its deliberations, that the opportunity is given to me and to every member of this Society to earry on, to uphold and protect the principles, the high and lofty ideals upon which this Society was founded. Principles and ideals which were established by it at the very first meeting in 1807.

It is quite apparent, from the early history, at the time the Dutch occupied Manhattan Island prior to 1664, the praetice of medicine and surgery had very little regulation and most of it was of low order. In 1664, when the English took over control of the Island, the Duke of York caused to be enacted more definite regulation for the practice of medicine. During the following eentury there are recorded various laws enacted for the control of contagious and infected conditions, also laws pertaining to military and eivil duties of the physician. In 1760 an act to regulate the practice of "Physick and Surgery" was passed. This was the first effectual measure to regulate the practice of medicine in the City of

New York. This law read: "No person whatsoever shall practice as a physician or surgeon in the said City of New York before he shall first have been examined in Physick or Surgery, and approved of, and admitted by one of His Majesty's Council, the Judges of the Supreme Court, the King's Attorney General and the Mayor of the City of New York for the time being or by any three or more of them taking to their assistance for such examination, such proper persons or person as they in their discretion shall think fit." If the person, so examined, was approved, a certificate was given him allowing him to praetice Physick and Surgery, or both, throughout the province.

It is recorded in the history of the Medical Society of the State of New York that the members of the medical profession in Saratoga County during the end of the eighteenth and early part of the nineteenth century attempted to secure the legal regulations of the practice of medicine by the establishment of a corporate State Medical Society composed of representatives of the different County Medical Societies which should have power of granting or refusing licenses to practice medicine. An act to incorporate Medical Societies for the purpose of regulating practice of Physick and Surgery in the State of New York was passed, as previously stated, April 4th, 1806.

The first meeting of the Medical Society of the State of New York was in February, 1807, at Albany, N. Y. The preamble starts in the following manner: "Whereas well regulated Medical Societies have been found to contribute to the diffusion of true science and particularly the knowledge of the healing art, therefore be it enacted." This law gave to each County Society the right to issue a diploma, after an examination, for the physician who desired to practice in a county. The State Society was given the right to grant a diploma and to review the aet of the County Society in case a diploma had been refused. History of the Medical Society of the State of New York states that "the practice of Physick in the State of New York was regulated by no public authority and of course was not in the happiest condition to promote the usefulness of the respectability of the profession." A representative from each of the Counties of Saratoga, Montgomery and Washington was appointed. A memorial to the Legislature was adopted. They, with the influence of other medical gentlemen, succeeded in establishing the State and County Medical Society.

This act may be regarded among the first efforts in this country to reduce medicine to a regular science by investing the privileges of medical men in the body of the members of the profession.

In a circular communication sent to County Societies, dated 1810, I found this quotation, "especially attention is called to the necessity for careful medical education not only for the students but also of physicians and for the purpose it is suggested that lecturers on medicine be chosen by the County Medical Societies to keep the members in touch with medical progress." This apparently is the first mention of our present Committee on Medical Education and Public Health which in the past few years has been so efficient and has accomplished so much under the present Chairman, Dr. Thomas P. Farmer.

The Medical Society of the State of New York in 1823 adopted a system of medical ethics "which breathed a lofty spirit of professional honor in the relation of the physician to his brother physician, the physician to the patient and to the State. There was scarcely a circumstance in the physician's relations to others which was not touched upon." It was of such a character that years later, when the American Medical Association drew up their original code of ethics, they adopted largely the principles enunciated in the code of the Medical Society of the State of New York.

In the brief foregoing quotations from the history of our Society, I have endeavored to give you a picture of the ideals, the principles and purposes upon which our Society was organized. These ideals, principles and purposes have transcended and endured since the very first meeting of this Society one hundred twenty-six years ago. Our Society today is composed of over thirteen thousand members. It is a federation of sixty County Societies, each represented by its pro rata share of delegates. We, the House of Delegates, are entrusted with the destiny of the State Society, the destiny of every graduate practicing in this State but far beyond that the future of the profession of this great State largely depends upon the ideals and principles which we maintain

Since the foundation of this Society I very seriously doubt that there has existed so many radical ideas, so much effort to change the very principles and ideals for which we have fought

as exist today. We must not forget for what our Society was organized. The primary idea was betterment of medical education. It established its ethics to create and maintain a better relationship of one physician with the other, a better understanding with the public. It has always endeavored to prevent and discourage quackery. It has stood for laws for the public welfare and public health. In its very incorporation it endeavored to place the control of the medical profession in the hands of the physician. The best medical authorities have always felt that the control of the practice and teaching of medicine must be controlled by the medical profession. There is no reason or logic existing why this principle shall not be maintained.

The activities of our Society are fairly well known to this House of Delegates but I am fearful that the great mass of the thirteen thousand members of our Society do not realize what the Society is doing for them. They are not aware of many activities of our Standing Committees.

There are no less than sixty-five members on the Standing and Special Committees including the Trustees and Executive Committees. These gentlemen give each year in the aggregate an enormous amount of time for the affairs of this Society and in so doing sacrifice their own personal time and work. Our Standing Committees are the backbone of the work of this Society. Our committee activities have greatly increased in recent years. Organized medicine is constantly being undermined. In times such as we are now experiencing it is the duty of every member of our Society to give his utmost support to organized medicine. Members of the House of Delegates, it is time that we sell our Society to ourselves.

It has always been necessary, since the first meeting in 1807, to be in touch with our State Legislature to see that the principles established in those early days were not destroyed. Many constructive changes have been made. It is far more urgent today than ever before that we support our Committee on Legislation. No committee can accomplish its purpose without the support of every member of this House of Delegates together with the loyal support of every one of the thirteen thousand members of our Society. What an influence on proper medical legislation against cults, antivivisection and other numerous inroads constantly being attempted, which destroy the very essentials of our efforts, could be made if each County Society would bring the potential influence of every member of its Society on the local representatives in the Legislature. Our Legislative Committee is a most important committee and must be supported. I take this opportunity of calling the attention of the House of Delegates to the necessity of increasing the influence of county units in legislative activities.

Our Economic Committee is a very vital institution in our Society. This Committee under the able leadership of its present Chairman has accomplished a tremendous amount of work and it deserves the praise of this Society. The bylaws of our Society state: "The function of this Committee shall be to conduct investigations, to gather facts, to make studies or surveys on the general subject of the relationship of the physician individually and collectively with the public. It shall review matters of general public information and study them both in regard to their effect upon the practice of medicine in private or institutional work. It shall concern itself with the financial aspects of the practice of medicine, throughout the State of New York, especially insofar as it affects the efficiency of medical service to the public. It shall concern itself with all economic phases regarding the practice of medicine in hospitals, private or public clinics, commercial organizations and other institutions established for diagnosis and treatment."

It is quite apparent the Committee is instructed to investigate, study and pursue fact-finding efforts in all the economic problems involving our present day practice of medicine. It is gratify-

ing to note that they, during the past year, "have concentrated on a few important pressing problems rather than attempt to carry forward to final action a multitude of considerations."

We are all familiar with the many attempts being made by laymen, by institutions, by insurance groups, by physicians not affiliated with organized medical societies, by health organizations and foundations, to change the present status of the care of the sick. Efforts, which tend to place medical activities and the practice of medicine in the hands of lay organizations, are dangerous and far more dangerous in the hands of commercial organizations. We must recognize the tremendous force of this movement.

We, the House of Delegates, will consider some of these problems during the ensuing session. Let us be calm in our deliberations. Our policies and our recommendations will be read and studied by many outside of our organization. What we do today will have important influence on the medicine of the future. If we are to have mass practice, let us so shackle it to such an extent that the individual will be protected and all medical activities will remain under the control of organized medicine.

COSTS OF MEDICAL CARE

THE REPORT OF THE SPECIAL COMMITTEE APPOINTED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK TO CONSIDER THE FINAL REPORT OF THE NATIONAL COMMITTEE ON THE COSTS OF MEDICAL CARE WHICH WAS ISSUED ON NOVEMBER 29, 1933.

This report was read to the House of Delegates on April 3, 1933, by Dr. Arthur W. Booth, chairman, and was adopted unanimously.

70UR Committee, after giving the matters before us careful consideration, is prompted to reiterate the truism that both the problem of quality of medical care and the problem of distribution of medical service are questions for the consideration of organized medicine. Your Committee believes that the Medical Society of the State of New York is the competent body to suggest measures and remedies for medical services in this State, and that the professional aspects of these problems can in the long run be administered adequately, and the remedies suggested can be made only by a personnel that by training and experience is competent to do the To place regulation and distribution of medical service in the hands of non-professional bodies usually results in an overwhelming increase in bureaucracy and a resultant augmented tax rate. Your Committee can find nothing in history or experience that obligates a community to give a perfectability of service simply because a part of the community demands it, when the costs would be beyond the ability of the community to bear.

Holding these views, we first present our general comments on the reports before us, and then offer substitute recommendations for your careful consideration.

GENERAL CONSIDERATIONS

When it is considered that the Committee on the Costs of Medical Care has been five years on its survey, and has expended a sum of money considerably over \$800,000, its final report is an extremely disappointing and empty document. The data assembled under its supervision are both interesting and informative, but they hardly required so much time or so much money for their compilation.

In the interpretation and correlation of the data in these miscellaneous reports there is much that we question. It is significant that a Committee with a total membership of 48 should have had to submit five separate reports. The controversy provoked in the Committee itself by the recommendations in the majority report do not lend an air of authority to them or hold out unqualified hopes of success for the projects advocated.

It appears too that the leaders of the Committee set out with a distinct bias for some of the proposals urged so enthusiastically in the majority report. Thus, group practice appears to have been from the start a pet idea of the directing forces in the Committee. This finds support in the fact that the Committee uses as its examples a few outstandingly successful organizations for group practice, but ignores the many instances in which such groups were not successful.

Another point on which there appears to have been a definite bias is the apparent desire of the Committee to place control of the practice of medicine in the hands of social agencies. majority report creates the impression that the medical profession is unprogressive and stands in the way of effective reforms in the distribution of professional services. All of its projects involve the establishment of elaborate superstructures about the physicians, who, after all, are the principal agents in any medical project. Even in the recommendations for group practice the majority report makes only casual mention of the county medical society clinics, and merely suggests them as possibilities for rural areas or small towns, although a number of medical societies throughout the country have undertaken work along these lines.

The Committee's drastic recommendations for group practice and for health insurance—whether voluntary or compulsory—are based upon opinion rather than fact. Over and against the evils which they admit have heretofore inhered in medical practice by organizations under insurance systems and by governmental health services, they state the mere opinion, unsubstantiated by any concrete facts, that these evils will cease to exist if the methods referred to are put into general effect here. The majority report opposes compulsory health insurance because of its unsatisfactory results in Europe and its inapplicability to American conditions, and then goes on to urge voluntary health insurance, which it repeatedly states to be the forerunner of compulsory health insurance.

The Committee emphasizes the indispensability of the personal relationship between doctor and patient, and then proceeds to urge systems of practice which must inevitably destroy that personal relationship.

The entire trend of the majority report appears to be theoretical and visionary, rather than practical and concrete. Without specifying exactly what it considers adequate medical care to be, it implies an exaggerated and extravagant standard of medical care. Its attitude toward preventive medicine, for example, is highly theoretical and implies that it is possible to prevent a greater percentage of illness than actually can be prevented with our present knowledge. Under the present method of medical practice, which the Gommittee considers ineffective and inefficient,

every preventive method of specific value has been put into effect with striking results (e.g., prevention of smallpox, typhoid, hookworm, diphtheria, etc.).

No amount of organization is going to prevent disease unless we actually have substantial prophylactic measures to employ. Failure to employ preventive service is not due primarily to the individualistic state of medical practice, but to the fact that prophylaxis is still a relatively new idea, and that many people are unaccustomed to go to a physician for anything but the relief of pain or actual illness. Furthermore, as the Committee itself said, "the actual effect of preventive medical services in reducing illness and disability is difficult to measure because of the multiplicity of factors involved." There is a constant increase in the use of prophylactic measures, and physicians undoubtedly receive more training in the use of such measures, yet for a long time to come curative medicine will be by far the major part of medical practice outside of mass public health measures.

Many general hygienic measures for prevention are as dependent upon economic improvement as upon the application of prophylactic measures by physicians, and the report ignores an essential factor when it dissociates the problems of health, particularly in reference to the prevention of disease, from general economic conditions.

The Committee acknowledges the inadequacy of present medical income, and acknowledges that the provision for adequate compensation to physicians is a major essential of a satisfactory medical service. It also states as an essential that no plan is economically sound which does not safeguard quality. Nevertheless, the insurance plan which it sponsors makes it impossible to safeguard quality or to assure an adequate compensation for the physician unless the costs of such insurance are made so high as to defeat the primary purpose of reducing the costs of medical care.

The so-called "costs of medical care" is but one small aspect of a large sociologic problem. Sickness insurance in the last analysis means both direct and indirect taxation. There is no immediate prospect that our national income will materially increase. It is more than likely that for some time to come there will be a continuation in the fall of the national income—a tendency which has been noticeable for some time. Thus, the national income

in 1929 was....\$82,500,000,000, in 1930 was.... 71,000,000,000, in 1931 was.... 54,000,000,000, and in 1932 was.... 37,000,000,000 (estimated).

The tax rate per capita has shown a distinct tendency to increase. Thus, from \$19.39 in 1903 it rose to \$124 in 1932, and it cannot sustain an added burden.

The money required to finance an adequate system of insurance would safeguard quality and assure the doctor suitable compensation would have to come from the State, and the costs of such a system would be so tremendous as to impose a terrific burden of taxation upon the nation. Since taxation must ultimately be borne by all the people, including the poor, this would be a transference and not a lessening of the costs of medical care.

Organization as such is not a thing to be worshipped. To call a place a medical center does not imply that it is a center of perfection. It is the character of the medical service that needs to be stressed, not the organization, nor its cost.

The conception that organized service through medical centers will insure a better grade of medical care is basically fallacious, since the quality of medical care depends ultimately on the quality of the practitioner. A good practitioner working alone holds out more promise of good medical care than a mediocre practitioner working in an elaborate center. The benefits which the Committee hopes to achieve through the creation of large centers are purely theoretical, while the losses that will accrue to the community through the destruction of the personal relationship between family and doctor are very real and very important.

It has already been observed by those interested in medical education that too much stress is placed upon laboratory procedures and not enough attention paid to clinical signs.

The concentration of medical practice in large centers would accentuate the tendency to diagnose by summarizing laboratory reports rather than by fine observation and sound clinical judgment. Furthermore, we are of the opinion that about 85 per cent of the diseases or affections with which people suffer are complaints that present no difficulties in diagnosis, but yield readily to treatment by the individual doctor in his private capacity. They are not susceptible nor amenable to mass treatment by health departments, centers or bureaus.

To place that portion of the public suffering from this 85 per cent group of cases upon the clinical resources of the country for elaborate "diagnostic workups" is to shoulder an expense that has no reasonable basis and its cost would be beyond the financial resources of the community.

On the other hand, the present system of medical practice, for all its disadvantages, is flexible. It encourages the physician to be independent, courageous and resourceful in his thinking. It is better adapted to periods of depression like the present than an elaborate, expensive organization. Actually, even the indigent here receive a better type of srvice than the poorer class in Europe under compulsory health insurance.

From the time of the French revolution in

1792 to the recent sickness insurance in 1930 it has been manifestly apparent whenever compulsory lealth insurance has been put into practice that (1) the mortality has not decreased; (2) the average days' illness has increased from seven to seventeen days; (3) there has developed a hinge amount of industrial neuroses; (4) malingering often reaches such extensive proportions as to call forth governmental reactions; and (5) there has been no corresponding increase in preventive medicine.

In addition, your Committee contends that a fall in the death rate from 18.6 per thousand per year in 1900 to 12 per thousand per year in 1930 is an adequate answer to the critics of the present system of medical care.

FUNDAMENTAL PRINCIPLES

Your Committee believes that in considering the questions before it certain fundamentals must be comprehended. We believe first that sickness is primarily the problem of the individual; second, that the most desirable goal to attain in earing for the sick is a continuation and an improvement in the quality of medical care; third, that preventive medicine is also an individual problem, and not capable of solution by mass efforts of health departments; and fourth, in most cases the medical problem is a local one, differing with locality.

Thus the medical service in large cities differs from the problems presented in rural communities, and no plan of medical service can be devised applicable alike to a city like New York or rural communities in a densely populated State like New York, and communities in sparsely populated areas like those of Nevada or the Dakotas.

Your Committee contends that no substantial evidence can be produced under which an idealistic system of medical service, irrespective of cost, could be devised, where medical service could be provided for all the people at all times and under all circumstances of equal type and quality. To believe otherwise would be to deny the lessons of experience learned in history and cancel entirely the human factors which come into play, for it has often been shown that a great many people in close proximity to adequate medical service never avail themselves of the opportunity it affords them.

RECOMMENDATIONS

Based upon the fundamentals outlined above, your Committee recommends to the Medical Society of the State of New York the following specific propositions:

Proposition Number 1

Under plans suited to the needs of the given community, and with an organization adopted and

approved by the organized medical group of that community—

The worthy poor of the community shall be treated free, and no charge shall be levied against them for any medical service whatsoever. They are properly the charge of the community, and the costs of medical treatment for them should be paid for from taxation. The physician who treats them should be paid, a minimum fee fixed by the community. To have the physician, who in most instances is also a taxpayer, carry the financial burden of their care in addition to paying his share of taxes is a social injustice because it imposes a double tax on the physician.

Indigents would be entitled to treatment in the organized hospitals of the community, or, under authorization of health departments or social service organizations, they would be entitled to treatment by physicians at their private offices or at the patient's home at special fee rates fixed for such cases. When such service is extended to this class group by voluntary hospitals, these should be paid from public funds. Indigents who are ambulatory cases and are served by the clinics and outpatient departments of voluntary hospitals also should be made a charge against public funds. The physicians who serve in the clinics and outpatient departments of the voluntary hospitals giving this service should be paid by the hospitals.

Voluntary hospitals should not render this type of service so as to make a profit from it, and since there would be no profit your Committee believes that the details of the hospital service should be so arranged and managed that there would be no incentive to increase this type of service beyond the reasonable physical capacity of the hospital to render such service. To better accomplish this purpose, your Committee recommends

Proposition Number 2

namely, that free service in all hospitals should be limited to those residing in a definite zone, and that the erection of hospitals in the future shall be in accordance with predetermined plans of hospital zoning, so that the anomalous situation of over-hospitalization in some zones and under-hospitalization in other zones may be avoided.

Proposition Number 3

There is in every community a group of people below the "comfort level," on whom the costs of medical care impose a heavy burden. These are self-respecting people of the salaried class in most instances, whose living expenses are met from their weekly earnings. For them the greater part of medical costs comprise charges for hospital and nursing care.

To lessen the burden of hospital and nursing care for this wage-earning group, your Commit-

tee recommends the adoption generally of a plan of hospital insurance, whose principles may be stated as follows:

- (a) Members of employed groups may receive for the payment of a small annual sum hospital care in semi-private accommodations for a period of 21 days in any one year, such care to include bed and board, general nursing service, x-ray and laboratory examinations.
- (b) All reputable voluntary hospitals and some proprietary hospitals be entitled to participate in this plan.
- (c) Except in emergencies, all admissions of patients cared for under this plan must be made through the patient's personal physician.
- (d) Certificates of membership issued to subscribers shall state specifically that the service does not cover the fee of the patient's physician.
- (e) In each community under the supervision of its organized medical group there shall be developed the details of this plan so as to meet local conditions and make it workable.

Proposition Number 4

Your Committee recommends that the Medical Society of the State of New York strongly express itself against any further extension of the federal government in hospitalization and medical service to non-war-incurred disabilities of veterans. From President Hoover's message on the Budget of 1934, governmental hospital services for veterans, their families and their dependents for illnesses and complaints that have arisen outside of the actual war service disability, will amount to \$452,000,000.

Your Committee contends that this medical service should be handled by the civilian medical profession and by the civil hospitals, and your Committee holds that even for the veterans with service-incurred disabilities, the necessary medical service should be done at the veteran's home city or town, in the civil hospitals by local surgeons, who should be paid for their services by the Government, thus lessening the costs of medical care for the war-disabled veteran. For the non-war-disabled, the cases should run their normal course in the local community where they occur.

And lastly, your Committee feels that it might not be amiss to call attention to the criminal waste in public funds in erecting governmental hospitals designed especially to treat war veterans, often located with no definite relation to the population and the needs of these very veterans, while long-established civilian hospitals, competently manned by physicians and surgeons in every city and large town of the country are now operating at only 63 per cent of their full capacity. These veterans' hospitals are not needed. The civilian hospitals could care for the veterans more efficiently and at less ultimate cost to the people and at much more convenience to the veterans themselves. This is another waste in the medical field of the nation and adds generally to the costs of medical care.

Proposition Number 5

Hospitals supported by public funds treat injured workmen in their cliarity wards and retain the fees allowed by the law of the State in such cases, including the fees earned by the physicians in some instances. Wage-earning workers are not paupers, and the law provides the necessary compensation in their cases. Industry pays the cost of workmen's compensation insurance, which is distributed as indirect taxation upon the community, and there is no social justice in hospitals supported by public funds extending medical service to a group for whose treatment provision has been made possible by other channels of taxation through the law of the State.

The Medical Society of the State of New York believes that there should not be an excursion of public hospitals into the field of treatment of workmen's compensation cases for industrial diseases. The fees allowed by law for the payment of medical charges should be given to the playsicians who serve this group of patients, so that the physicians can better do their share toward serving those others in the wage-earning scale whose inability to meet medical service charges

require adjustment of their bills.

Your Committee recommends that the Medical Society of the State of New York take action and urge upon the proper State and municipal officials the discontinuance of treatment of workmen's compensation cases by all hospitals supported by taxation, except where in a given community there are no other hospital facilities, and except in such hospitals as treat workmen's compensation cases at full cost, charging same and providing for the payment to the physician treating such cases of the fees allowed him by law.

Proposition Number 6

Your Committee recommends that the present method of treatment of tuberculosis, insanity, mental defectives and epilepsy be continued as heretofore, and that the treatment of crippled children under the direction of the State Department of Health be continued, but that such treatment be carried out under a program which shall include the employment of the local physicians in the treatment of the cases.

Finally, your Committee urges that the Medical Society of the State of New York take measures to see to it that the State Department of Health does not become an agency for the treat-

ment of such crippled children.

Proposition Number 7

Your Committee believes that the costs of preventive medicine can be lessened, and that the

personal relationship between family physician and patient can be maintained by the adoption of the Gieb-Vaughn-Detroit Plan of Public Health Work. Under this Plan physicians are paid for the services they render, preventive medicine is enhanced, and as far as the Plan has been at work there has been a reduction in both mortality and morbidity. Graduate education of physicians in preventable diseases has found encouraging support. Moreover the costs of preventive medicine to the community are reduced. In other words, people receive more and better service and the taxpayer pays less than for any other plan now in operation. The Plan decentralizes rather than centralizes service. It provides for the abolition of, rather than the increase in, clinics and pay clinics. While the feasibility of this Plan has not been recorded in the report of the Committee on Medical Costs, nor has it been evaluated, your Committee recommends that the House of Delegates approve the principles underlying the Detroit Plan as a means of distributing the burden of medical care and making preventive medicine an active, live issue for all practicing physicians in the community.

In conclusion, your Committee endorses and quotes from the Commission on Medical Education, whose report was also before us for study,

the following:

"Allowing for the defects in present methods, there are fundamental advantages in the American form of practice which need to be strengthened. It is not necessary to substitute for the present efforts a paternalistic plan, ill-adapted to the philosophy of American life, but rather to encourage the evolution of a pattern which will embrace the desirable leatures of our present methods and the correction of their defects. Some efforts are being made to provide standardized service on a mass production basis, reflecting recent practices in industry. It is a fundamental fallacy to base any program upon the assumption that the human being who is the unit of practice can be, or is likely in the future to become, a uniform, standardized organism. Voluntary sickness insurance has always led to compulsory insurance. As programs of insurance become compulsory they are inevitably made a part of social legislation and are subjected. The fore, to the hazards, advantage of the subject of locality in the subject of loca

Respectfully submitted,

(Signed) ARTHUR W. BOOTH, M.D., Chairman GEORGE W. COTTIS, M.D. CHARLES H. GOODRICH, M.D. EDWARD E. HALEY, M.D. SAMUEL J. KOPETZKY, M.D. JAMES F. ROONEY, M.D.

FINANCING SICKNESS

By FREDERIC E. ELLIOTT, M.D., BROOKLYN, N. Y.

From the Committee on Economics of the Medical Society of the State of New York. Read at the regular meeting of the Medical Society of the County of Kings, March 21, 1933.

THE profession of medicine in its very nature can never be solely a mercenary pursuit. Of all the emoluments that come to him who serves the sick and injured there is none so precious as the generous gratitude from the heart of the one who is served, or from an understanding kinfolk. It is this element of reward which distinguishes the work of a physician from all other occupations. It makes men and women meet the hardships, the personal sacrifices and the exacting demands of unending years of effort with unfaltering devotion to duty. When money is the sole motive, the practice of medicine is not a profession.

There are few, if any, who are able to maintain themselves in the practice of medicine independent of any remunerative reward from the rendered service to the sick and injured. "wherewithal" to provide equipment and supplies, office and transportation, and to meet the other incidental expenses, to say nothing of continued intellectual growth, must be obtained from professional occupation. And who can deny the justice of the costs of customary comforts, food, clothing and shelter, and a reasonable financial security for the physician and his family, out of his earned recompense? The obligation of the patient is a true debt: the fee-for-service is a just claim. Discord grows in the relations between physician and client when the debtor relationship is loosely or not explicitly understood

"What-should" and "how-can" the patient pay? What is a fair and equitable value of the rendered services? Much uninformed and confused thinking has been done on these questions. public mind has been misled by the magnified complaints of a few disgruntled, dissatisfied, unidentified persons publicized in the recent reports of an unofficial, self-constituted committee "on the costs of medical care." There is nothing in the reports to indicate that this committee concerned itself with the investment-costs incidental to medical education; nor did they apply themselves to an analysis of the essential costs of maintaining adequate medical service. problem of what return the doctor should justly receive on his investment and labor, "the doctor's bill," remains with us.

Financially, our people are of three ranges the indigent, who depend on charity; the wealthy, who have the means to get what they want; and the great "in-between" group, who are of various and variable solvency.

The doctrine that the indigent are properly the wards of the community has been established in our State in the Social Welfare Law. The poor, to the eternal glory of our profession, have never

been denied medical care because of their inability to pay for it. However, when the Welfare Law is perfected and made to apply equitably to the urban, as it now does to some of the suburban and rural localities, the burden of financing sickness in this class will be shifted from the individual members of the medical profession to the public tax funds, where it properly belongs. Sickcare presents no monetary problems to the wealthy.

There are millions of people, between the indigent and wealthy, who, when they require medical care, need guidance in "how to pay for it." Many among them are not currently in possession of liquid assets to meet immediately the expenses of such an experience. The problem of "ways and means" becomes acute and commonly is complicated with emotional disturbances of anxiety and fear. We of the medical profession have been derelict in the consideration of this phase of their troubles. The problems of financing sickness confront these millions.

A changing national psychology necessitates a change in the set of the professional mind toward the economics of sick-care. We engage in a discussion of matters which involve or hazard the patient's life without hesitation or embarrassment, at the same time, we are timid and fearful of undertaking to arrive at an understanding on a matter which merely involves the pocketbook. fear to profane the nobility or professional character of our work by speaking of money and helping to plan the money matters of sick-care. Certainly, we are unprepared to direct the patient or his family to trustworthy hands where they can find financial assistance to self help. conventional, unbusiness-like attitude toward the patient's obligation for sick-care is unintelligent and unsuited to a people who are replacing sentimentalism, "make believe" and hypocrisy with frankness, candor and realism.

Time-honored custom has made "credits," "collections" and "accounts receivable" the by-products of sick-care. Most of the criticism leveled at the medical profession, and all of the agitation about the "cost of medical care" are rooted on the debit side of the doctors' ledgers. It seems stupid to continue to incubate trouble for ourselves in these old "joke-books," in which we "wish-charge" with hope, and "discharge" with disappointments and despair. On the ill will cultivated by unpaid medical bills, the so-called "health economists" plant the seeds of socialized medicine. counts" do not germinate or generate unhappiness and misgivings. Some program must be devised which will eliminate all pending money obligations from the direct relationship between the physician and the people whom he serves. The millions of "white collar" people want quality service, and a thrift or budget payment plan. The husiness aspect of sick-care is destined to be modernized—in our hands, or by others.

Insurance will not provide that modernizing change. In theory, a measure of security, against the excessive financial stresses occasioned by sickness, seems attainable by the distribution of the costs over large numbers by one or another scheme of insurance. In practice, the fundamental economic fallacy of such insurance develops because of two inalienable features. First, of its own nature, there is added, to the necessary carecosts, a very considerable burden of "administration machinery" to solicit, collect, investigate, distribute, examine, adjust, police, and otherwise conduct such insurance. Second, human nature cannot be rectified by statute, and malingering, fraud and corruption desecrate all such humanitarian social experiments whenever and wherever tried. The collapse of the "Workmen's Compensation Law," threatened in various commonwealths today, is a clear demonstration of these truths.

Hospitals, so-called "guilds" or group practice have been proposed as the panacea for the troublesome financing of sick-care. The wasteful, ex-travagant building constructions and the high per diem operating expenses in our public institutions clearly indicate that our politicians are not to be trusted with the problem. To the quasi-private hospitals, who solicit gifts in the name of charity, to these we look in vain for exemplary economic administration-to reduce the costs of sick-care. By their own admissions, they are habitually in a state of financial distress. Fifty-five institutions in New York City report deficits of eight thousand to three-quarters of a million dollars for the year of 1932. Charity to the poor and indigent is honelessly confused with service to the solventcconomics muddled by sentiment—injudicious good mired in waste! The intellectual beacons to guide the way to sane financing of sickness do not shine in the administration offices of our hospitals. No system of sick-care, built around the presentday hospital administration, can prove thrifty or sound. The over-growth of medical dole and its heartless exploitation of the medical profession has come to a crisis. The "angels" who lifted the deficits have flown away. Revenue from which to meet the mounting deficits is the driving necessity of another transition from medical dole to medical practice-to the beginning of organized established competition for the sick-care of the selfsupporting classes—to the desertion of charity for the pursuit of profit-to the provision of medical care for the masses at a cheap price to cover the losses of mal-administration.

The so-called "guilds" and "groups" have made no significant demonstrations. The idea of "mass

production" methods of industry applied to medical service is immaterial, incompetent and not worthy of consideration.

The doctor personifies the key to the problem of financing sickness. He can open the way to a solution. His intelligence protects life through the complexities of disease-diagnosis and treatment. He must broaden his responsibilities and guide his people through the other problems incident to the time of sickness. The logical approach to the financial problem of sick-care is that of meeting it where it occurs-face to face with individual responsibility-keep it there and work out the best solution possible to each case. We of the profession must face frankly the fact that it is our task to render service, as, if, and when needed, to every one of that vast "inbetween" population, at a cost within the pricerange of each. The medical man must recast his ideas about "money matters" of sick-care; he must make readjustments to the present day social structure, and state of the popular mind. The challenge must be met, or we face the consequences of another "noble experiment"—the socialization of medicine with fanatic reformers and politicians at the controls. The day is here when the medical man must be economist as wel' as physician to his people.

An important item in the cost of medical care is the reward due the physician. The value of professional service cannot be measured by any of the ordinary standards. If calculated to give a reasonable return-on and recovery-of the investment cost of education and the expense-of maintenance, only the few could afford medical care. The reasonable worth of it must rest upon appreciation, the standard of living, and capacity to pay for medical service as for other needs. The natural impulse to feel grateful and the resources from which to make tangible remuneration are not possessed by all alike. The fee-forservice, diversified to the circumstances of the individual, is economically sound and has stood the test of time. It is the only system which automatically adjusts to the unevenness of income and resources, from one community to another, and from one time to another in the same community. It has successfully distributed the cost of medical care over large numbers without adding complex administrative machinery and the "poundage" of waste and countless "jobs" to the national sickcare burden. In a population of many millions with shifting fortunes and vagaries of pretense and "false fronts," it is to be expected that wrongs occur to both parties. Selected, isolated instances of such wrongs have been grossly magnified and publicized-to the naive purposes of certain persons. The defects of the fce-for-service system are insignificant, the benefits are indisputable. The preservation of self-respect is assured and a keener sense of individual responsibility encouraged by the exercise of personal initiative and self-reliance. The social agitators may well let the old traditional generosity continue to favor the people of moderate circumstances. Practically, the value of medical care is what the patient is willing and able to pay; no more and no less.

It has not been the custom of medical men to find a prompt, explicit understanding on the matter of fee and the time and method of payment. To our Fathers this seemed commercial. They handed down the unbusinesslike office habits of the day. It is in order and entirely ethical to attend the patient, win his appreciation and gratitude and then to dumbfound him with a 'bill for professional service." Our citizen neighbors are ready for a newer "business-ethics" in sick-care.

There is a proper and right time to establish the value of professional service. When one desires or needs something, he is at the peak of his appreciation. This is as true of medical care as of other things. The value fixed by the appreciation of today quickly fades with the passing of time and the coming of newer desires and needs. It is not ingratitude but a natural process of life that robs the old account for medical service of its "demand value." Conversion of an indefinite implied obligation into specific terms of settlement obviates misunderstanding. A written acceptance or acknowledgment of value, with a promise to pay, will make it possible and practical to take bookkeeping and bill collecting out of the practice of medicine. Determination of value left to the unwritten "implied contract," to pay an unspecified sum, opens the door to abuses by the unscrupulous. These abuses have occurred and have brought criticism upon the profession. It is more ethical and a better policy to give kindly, friendly counsel in a frank discussion of the material affairs of our work. The written "promise to pay" preserves the appreciation and good-will better than the fading memory and the nagging "statement of account." A mutually understood and agreed-upon "value" is the first step to a sound "credit" in medicine. Credit extended by the physician for rendered services can be made to have a true equivalence to money.

What is credit? Credit is the unknown quantity, "X," the variable, in many of the affairs and equations of everyday life. Economists acknowledge credit to be essential to the transactions of Industry and Trade. It is no less so to the provision of professional service. Credit is the complement of currency. Use of it results in immeasurable good, misuse leads to irreparable harm. Without it the world stagnates. Unfortunately, we of the learned walks of life rarely analyze or comprehend the constitution or functions of credit. We employ it with little skill and great

indiscretion.

Bookkeeping with the entry of a fee-charge is not credit. It is merely the memorandum of a

claim for service. Common Law says, "...in every sale where the price is not fixed there is an implied agreement that the buyer shall pay what the goods are reasonably worth." This principle would seem to establish the status of the professional fee. However, an agreement is in fact a contract, and a contract is not valid if it lacks any of the essential legal elements. Acceptance of a service does not carry with it the assent to the debt unless the "reasonable worth" of the service is understood and known. If, with assent to the debt, there is agreement that it shall be paid at some fixed, future time, that is credit. Credit in the financing of sickness should be made to conform to the rules of law and to standard methods of business and banking practice.

Payment is lawfully and properly due at the time when a professional service is rendered. All the discussion about the costs of medical care is nothing more than the indirect indictment of our old-fashioned, indefinite, haphazard, slipshod and methodless administration of the purely business side of medical care. When the patient is to be favored with a gratuitous service, he should know that fact at the time when his appreciation is greatest—at the time when the service is rendered. Many among the "in-between" millions are not able to pay at the moment but there is no honest person who cannot acknowledge the obligation and arrange a settlement which will give his credit a true monetary value. The financial obligation incident to sick-care must be faced with a little less sentiment, with a little more backbone, and with candid, rational frankness by the public and by the members of the profession. The troubles which habitually grow out of so-called credit for medical care are incurable. Prevention is the only sane treatment.

Bankers have provided service to virtually every field of credit except that of medicine. Adequate medical care—the fourth basic necessity of life-presents credit requirements of a volume second to no single Industry, still there is no established system to provide that service. Time does not permit the discussion of the reasons This undeveloped opportunity is now under survey. In fact, in a small way, a start has been made to set up such service. In Boston, Chicago, New York and elsewhere, firms have taken up the specialty of "small loans for sick care." A growing popularity with the public and the professions is indicated by the constantly increasing demands for service experienced by all of these firms. Their activities have been limited only by their available capital. And so arises a new problem.

What shall organized medicine do about it? What should be the attitude of the individual members of the professions? It might be well to recall what has happened in other directions. Medical education has gotten out of hand and

the pedagogists have undertaken to make book shelves out of grey cells. Brains which should be taught how to think and how and where to get the materials for thought, are made impractical with a supersaturation of unorganized and poorly related medical culture. Hospital development and administration, inherently a service to supplement the physician in the care of the siek, now brings the threat of organized, cheap impersonalized competition-the supplementing agent now proposes to substitute for the physician, introducing the era of medical practice by nurses and technicians-and they propose to sell their wares by straight commercial advertising. It is not irrelevant to point out that the control of eredits in Industry has exercised a large influence upon those engaged in Industry. Therefore, it would seem wise that medical men participate in the shaping of the growth of principles and methods of procedure while this new enterprise is in its formative stage of development-at least by some program of inspection, supervision or regulation, if not in fact by becoming an integral part of it through participation in ownership.

Volume 33

Number 8

The Committee on Economics of your State Society has concerned itself not so much with the mechanics of the details-notes, discounts, bookkeeping, etc., as it has with the fundamental prineiples which must govern the growth and funetions of medical credit financing. Provision of fair and open competition on rules that insure reliability, stability and security has seemed to promise the more wholesome growth of this enterprise, and we have preferred to consider these rather than to advise endorsement or express preferment of any one firm or system of small loan procedure. Experience in a working test must justify or condemn the particular points of method and practice. Each individual firm should stand or fall on the character of service which it renders. In every case, such service must conserve and promote the spirit of good will between the public and the professions who serve the public. The traditional humanitarianism of the medical profession cannot be put aside for the "glass eyed" banking of commerce. The costs of this service can be met out of the losses formerly suffered by physicians in the loose and less businesslike methods of the past, and with little or no increase of cost to the public, who are thus given an added service of financial help in the procurement of a necessity of life.

The Committee feels that banking psychology must make certain concessions toward the characteristics peculiar to our "credits," and it is frankly conceded that physicians must make many adjustments to fit a newer and better plan of making adequate medical care easily and readily available to all of the solvent people.

Some members of the Committee visualize a future development of the financing of siekness

which will take the form of an organized system of secretarial service. A service to which the nublic can go for guidance in the business matters of sick-care. Where they can obtain advice on the setting up of thrift accounts to anticipate the unpredictable accident or sickness-a need which is inevitable to 94 per cent of the "in-between" population, according to statistics. where the public may find guidance on the budgeting of health expenses and where they may establish eredit accountability. Where they may prearrange for the fixed, periodic payments of their medical bills out of earned, current income. The day may come when each physician, as he sees his patient, will receive immediate compensation, either by money or its equivalent in health-creditcurrency, scrip or a draft written on a credit account. On the latter, the patient will acknowledge the receipt and value of the medical care, and payments thereon will be made through the Financial Secretarial Service according to prearranged terms by fixed, periodic payments suited to the ability of the family income and resources. The physician, instead of keeping books, will deposit the "acknowledgments" with the finance eompany of his choice, much as he now deposits his ordinary bank checks.

Advantages of such a system will accrue to the public and the professions:

To the Public:

 Adequate medical care will be available to all who are solvent—either by resource or earning capacity. The unpredictable, inevitable need is prepared for.

2. Progressive development of the art and science of medicine, and continuity of the present standards of quality of service will be assured.

3. The burden of a bureaucratic sick-care insurance will not be imposed upon either Industry or the Taxpayer.

 Freedom of personal choice of professional medical care will be assured—with continued individual self-reliance, independence and self-respect.

5. Busy-body sociologists will be kept out of the poor man's bedroom. He and his family will not be made, like guinea pigs, the material for one or another "social or biologic experiment."

6. A low family income will not draw a class distinction in a race of free people: a politically controlled communism will not be set up: and the intimacies of the home and family life will not be made public property for those who live on statistics.

7. Those who do pay will not continue to pay more because those who ought to pay are not

made to do so.

To the Professions:

1. Success will remain the award to effort and ability arising out of fair and open competition

rather than a plum of preferment, political, panel or otherwise.

- 2. There will be escape from the vexations of the business side of medical care: bookkeeping and bill collecting will be taken out of the practice of medicine. The "doctor's bill" will fade out of the memory of man.
- 3. The rationalization of the professional fee to the income of each family, based upon full knowledge of income, resources, and justice.
- 4. When a debt has been incurred for medical care, it will be a debt to the "bank," not to the doctor. The old unpaid account will not stand between the physician and his patient—to drive the patient elsewhere if a new need arises.
- 5. The physician's income will be more liquid: his accounts receivable at the Finance-secretarial office will have a loan if not a cash value.
- 6. Plans for educational and recreational refreshment will be more feasible.
- 7. The "dead beat" will protest volubly—but will be made to pay.

To sum up:

The obligation to compensate professional medical care is being faced with greater frankness. Public attention is focused on the problems incident to the provision of adequate medical care and how to pay for it. Some of the proposed schemes are socialistic and some are patently communistic. Against these we propose a truly American, thoroughly democratic plan for a free, independent, solvent people, who, in the pursuit of life and happiness and the exercise of their natural rights, are privileged to select, without paternalistic guidance, the food, the clothing, the shelter and the medical care of the personal individual choice.

Meeting the expense of sick-care by small loans or by a program of periodic payments, through some responsible agency, is the rational solution of the problem of financing sickness.

Responsible representatives of ample resources

have indicated an interest in the possibility of such a program on a national, fully capitalized basis—with ownership participation by the professions, if that is desired—provided:

- 1. That organized medicine put the stamp of approval upon the general idea that the business of provision of medical care should be taken out of the practice of the profession of medicine.
- 2. And that organized medicine declare such service desirable.
- 3. And finally, that organized medicine indicate a willingness to assist, at least in an advisory capacity, to help plan and work out the details of operation and to safeguard the ethics and the traditions of the honored profession.

To us of the medical profession there is much promise that happier days are ahead. Congress and the President have concluded the Veterans' hospital and sick-care "racket." Commissioner Vaughan of Detroit has pointed the way to participation of the whole profession in public health work with the closing up of health department clinics. Steps have been taken to bring about the requirement of the certification of indigency as a condition to "free medical care." The Public Welfare Law makes the poor the wards of the community and the burden of the "medical dole" is in the way of being lifted from the shoulders of the profession. The idea of decentralization in industry is taking root in the minds of those who plan the care of the sick. There is the hope, at least, that the business of provision and the practice of profession may be made to complement, not confuse and confound each other. And finally, there is the beginning of consciousness that organized medicine shall proceed in an advolution to real unity of interest—to a form of organization which can discipline that free-lance individualism which we know to be animated only by selfish motives. We are coming to the day when the profession of medicine shall have the machinery to think collectively and to effectively act with its full potential power for the common welfare of mankind.

MAXILLARY SINUSITIS: PATHOLOGY*

By ANDREW A. EGGSTON, M.D., NEW YORK, N. Y.

In a recent publication a new classification of the pathological changes resulting from chronic infection of the accessory nasal sinuses was outlined. This classification serves as a basis for a revaluation of the processes involved in the production of permanent changes in the soft and bony structures of the nose and sinuses. The bases of these studies have been surgical tissues and post-mortem specimens from the

Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932. maxillary, frontal, ethmoidal and sphenoidal sinuses. In these cases the clinical histories, operative procedures, laboratory and x-ray findings have been correlated with the histological pictures presented by the tissues removed. This correlation is very essential to the understanding of the anatomical and pathological studies of any sinus disease.

The pathological anatomy resulting from chronic sinusitis has frequently been described and has received a varied terminology. In most

cases of chronic sinusitis, the clinical manifestation expresses altered physiology, which is the sequence to microscopically deranged histology the exact nature of which has not been elearly defined. The tissue changes observed have led to an explanation of the pathology involved. This should be of fundamental value in understanding the processes which may result ultimately in the clinical application of this knowledge to the treatment of sinusitis.

The tissues of the sinuses are supplied with blood by arteries and drained by veins and lymphatics, which are unique in structure and physiology. The blood supply is particularly excessive and peculiarly sensitive to the extrinsic and intrinsic changes to which these membranes are exposed. The circulation of fluids through these tissues varies momentarily, and a suitable adjustment to altered conditions is of prime importance. Vascular lesions in the tissues taken from the sinuses have been so universally observed that an attempt to explain the changes in the adjacent structures has been made with the circulatory system as a basis.

Repeated acute infections in the nasal sinuses is usually the basis of chronic tissue changes. The pathological histology of acute sinuisitis reveals practically the same vascular and cellular reaction of the soft tissue as occurs in other locations of the body. Briefly, these changes are dilated and congested blood vessels with cellular stasis, migration of leukocytes into the tissue, the appearance of lymphocytes, plasma cells and other cellular forms in the walls of the vessels and the immediate perivascular tissue, associated with diffusion of serum into the adjacent structures. These reactions occur primarily in the walls of the blood vessels and perivascular spaces, and secondarily The acute inflammatory in the soft tissues changes disappear as the irritation subsides, but it is an axiom in pathology that every inflammatory process, however small, leaves a disturbed tissue relationship, usually in the form of an increased fibrous tissue content. It is also known that the fibrosis leaves the tissue more sensitive to subsequent attacks. Repeated infections and inflammation ultimately produce fibrous changes of pathological importance. If the chief change in acute inflammation is vascular, it logically follows that the greatest chronic changes are also vascular. The distribution of these changes may be arterial, venous or lymphatic. The type of chronic pathological changes found in the soft and bony tissues depends upon which of the vascular channels is involved.

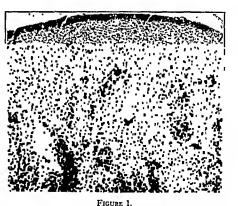

Types of Chronic Sinusitis

The acute processes of sinusitis are not easily demonstrated, as few surgical specimens are available for study. However, enough of the changes have come under our observation in acute

sinusitis to demonstrate the pathological processes responsible for the gross changes which are found in the terminal stages. These stages are the type with which this presentation is concerned and consists of the following three varieties:

- Hypertrophic or polypoid sinusitis is characterized by thickened and edematous changes in the mucous membrane and periosteum, and is usually associated with polypoid masses of the soft tissue and rarefaction and osteoporosis of the bone.
- 2. Atrophic, fibrotic sclerotic and arteriosclerotic sinusitis is characterized by an increase in the fibrous connective tissue in the stroma, thinning of the mucous membrane and metaplasia of the surface epithelium, associated with thickening of the periosteum and a condensing osteitis.

3. The third type of sinusitis results from a combination of the hypertrophic and fibrotic changes in the same patient or even in the same sinus cavity. This type is characterized by rugae and sulci, with the production of a papillated type of membrane.

Section of polypoid sinusitis showing desquamotion of the surfoce epithelium with loss of cilia; and edema with diffuse inflammolory recotions in the tunica-proprio. The perivasculor manteling of cells is illustrated in both the cross and longitudinal sections of the vessels.

Hypertrophic Sinusitis. — Hypertrophic sinusitis is the most common variety and is characterized by an increase in the volume of the mucous membrane and is commonly called polypoid sinusitis. In the earlier stages there is an increase in the thickness of the epithelial layers, with some cellular infiltration, chiefly lymphocytes, large amount of mucin secretion and desquamation of cells, with loss of cilia and ultimately metaplasia of the epithelium. The stroma shows edema with marked infiltration of mononuclear wandering cells, consisting chiefly of lymphocytes and plasma cells, and in some instances, eosinophiles. The

cellular reaction is most marked in the walls of the veins and lymph channels and the immediately adjacent stroma, presenting definite phlebitis and lymphangitis, with varying degrees of periphlebitis and perilymphangitis. (Figs. 1, 2 and 3.)

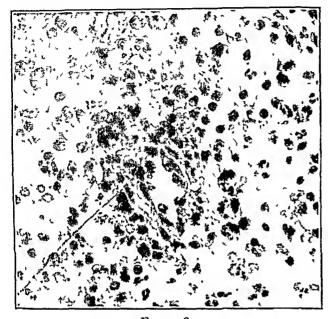

Figure 2.

A higher magnification of a lymph vessel showing perivascular infiltration.

In the later stages there is marked edema of the tunica-propria with separation of the fibrillar network. There is an increase in the quantity of fibrous tissue with a decrease in the amount of elastic tissue. This turgescence of tissue continues until there is a production of polypoid masses. The surface epithelium becomes thin, due to the pressure, and the mucous glands show cystic degeneration, due to obstruction of the excretory ducts from the pressure within the stroma. In some areas mononuclear cellular infiltration becomes so intense as to simulate lymph follicles. These have been designated by Fleming as secondary nodules. Fig. 4.)

The vascular changes consist of inflammatory infiltration of the veins and lymphatics followed by an increase in the fibrous tissue which replaces the smooth muscle and elastic tissue, consequently reducing the resiliency and contractility of these structures. These changes produce a partial or complete obstruction of the venous and lymphatic channels, resulting in interference with the drainage of the areas supplied. (Fig. 5.) This increased stagnation of the fluids results in further extravasation into the fibrous tissue spaces, increasing the tendency to polypoid hypertrophy. In some instances, actual thrombi can be demonstrated in the veins, producing the obstruction. (Fig. 6.) As the result of localized thrombi there will be dilata-

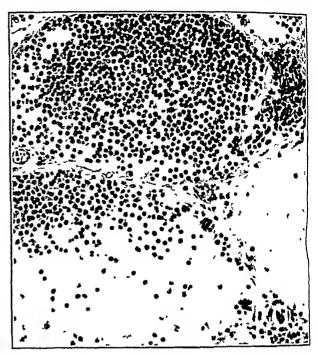

FIGURE 3.

tion of the vessels proximal to the obstruction, which makes more difficult the true interpretation of the processes involved.

The blood vessels in nearly all instances show varying stages of inflammatory process, representing acute, subacute and chronic changes. This manner of producing polypoid changes in the nose is similar to the

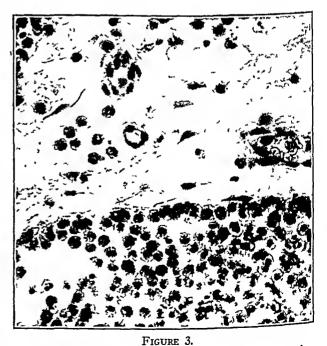

Plate B. Same as A, with higher magnification showing eosinophiles in the vessels.

processes involved in the production of polyps in the larynx, cervix, intestinal tract and rectum. Hemorrhoids are polypoid masses containing thrombotic and dilated veins with edema. As a result of venous and lymphatic obstruction, there will be changes in the soft tissues and involvement of the periosteum and bone. The perios-

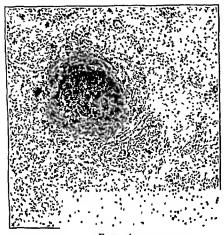

FIGURE 4.

Shows edemo of the stromo, morked mononucleor cellular reaction, with the formation of a secondary lymph follicle.

teum becomes thickened and edematous; its fibers are widely separated by fluid, and ultimately the bony structures show signs of absorption and osteoporosis. The bone may become necrotic and sequestrated, and in some instances, septa or plates disappear; in other places, bony cysts, spurs and deviations may result. The normal growth of bonc is due to the activity of osteoblasts (Fig. 7), which may have the faculty of absorbing and depositing bony salts from the circulating fluids. If the circulation is interfered with, bony absorption may replace formation Giant cells, so-called osteoclasts (Fig. 8) or wandering calls appear in great numbers. This type of lesion is usually easily diagnosed clinically, as there is a glistening, pale, polypoid, edematous thickening of the membrane, producing rather gross lesions which can be easily recognized. (Fig. 9.)

Fibrotic Sinusitis—The atrophic or fibrous type of sinusitis presents a picture which is an exact counterpart of the hypertrophic type. A decrease in the volume of tissue is characteristic, however, there may be a gross thickness of the membrane if the volume of scar tissue is great. In the earlier stages, there is very little atrophy,

but in the later stages marked reduction of the soft tissue and bony structures occurs.

The fibrotic type of sinusitis in its most ad-

FIGURE 5.

vanced stage simulates the changes found in ozena, with a loss of secretion, crust formation and a putrid odor, but many cases do not progress to this stage of severity. Undoubtedly, the processes involved are of a similar nature. In the milder cases of fibrosis, there is no necrosis of tissue, little interference with glandular activity

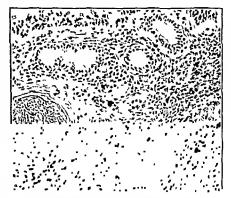

FIGURE 6.

inflammatory infiltration in the adjacent vessels.

and consequently no actual crust formation, and the putrefactive odor is usually absent in the early stages. Grossly, the membrane appears tenaceous and offers more resistance to instrumentation.

FIGURE 7.

tion. In some areas the epithelium of the mucous membrane may be thickened, forming papillae, while in other areas it may be thin and become squamous. The basement membrane beneath the surface epithelium is thickened and hyaline and forms a very distinct hyaline band of tissue. (Fig. 10.) There is usually a marked condensation of the tunica propria characterized by dense bands of fibrous connective tissue. In the early stages this is fibroblastic, but later it shows marked hyaline degeneration. This is particularly noticeable in the basement membrane and around the glands. The secretory glands are usually small, atrophic and inactive. If the efferent ducts are obstructed, they become cystic. The cellular reactions of the stroma usually consist of fibroblasts, lymphocytes, plasma cells and other wandering monocytes. Lymphoid collections are rather common and frequently show a central arteriole. There is generally a greater simplicity in the variety of the cells than is found in the hypertrophic type.

Figure 9.

Early polypi showing edema, dilated and thrombotic vessels with perivascular infiltration.

The most striking changes occur in and around the afferent blood vessels in contrast with the changes occurring in the efferent or drainage vessels in the polypoid type. The vessels involved in fibrotic sinusitis are the arteries and arterioles (Figs. 11 to 14), which supply nourishment and not the veins and lymphatics which drain the areas, as in the case of the hypertrophic type. Usually, endarteritis, arteritis or periarteritis can be demonstrated. In the earlier stages there is considerable cellular reaction around the vessels and an increase in the fibrous tissue. In the later stages the vessel walls are distinctly thickened, the lumina of the vessels are decreased and in some instances arterio-

sclerotic changes with complete occlusion of the vessels occur. (Figs. 13 and 14.) There is degeneration of the elastic fibers and of the smooth muscles in the walls of the vessels, which interferes with the resiliency and elasticity of the vessels. The veins and lymphatics show decreased fluid content and in some instances are collapsed. There is irregularity of the bone, owing to the

perichondric and periosteal inflammation, which results in alternating areas of cartilage and bone formation interspersed with areas of absorption

and in the more acute processes, necrosis of the bone. If the arteriolar vascular involvement is of a relatively subacute nature, so characteristic of syphilis, there will be marked necrosis of the soft tissue and bone. In atrophic sinusitis the process is of a more chronic nature, and necrosis occurs only in the advanced stages, on account of slight

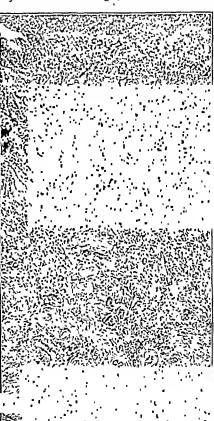

FIGURE 11.

or no increase in the volume of the membrane and lack of objective signs. This type of sinusitis is frequently overlooked by the clinician and a favorable opinion usually follows even though there exists a low grade sinusitis which is probably of a more severe consequence than the hypertrophic type. This type is frequently the primary pathology of a cardio-renal-vascular disease and

the type usually found in retro-bulbar neuritis. (Fig. 15.)

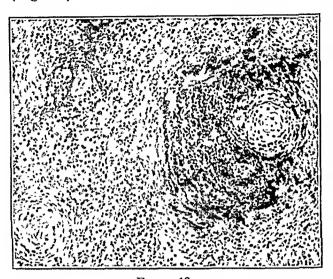

Figure 12.

Shows early stages of end- and peri-arteritis with manteling of the vessel. In the lower left hand border an occluded fibrotic arteriole is shown.

Combined Type of Sinusitis.—The third, or combined type of chronic sinusitis consists of an involvement of the afferent and the efferent vascular channels. The arterioles as well as the venules and lymphatics are involved in adjacent areas of the mucous membrane. The surface of the membrane reveals a rather nodular or trabeculated appearance produced by alternate areas of edema and hypertrophy, interspersed by fibrotic or atrophic zones. As the fibrous tissue contracts,

Figure 13.

Figures 13 and 14 show sections of antral mucosa with marked fibrosis of arteries and of the Tunica-Propria, and complete occlusion of the vessels.

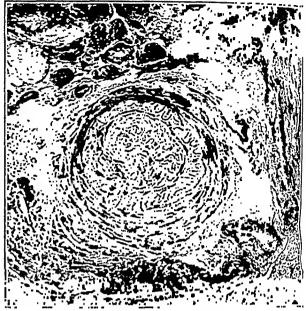

FIGURE 14.

the hypertrophic nodules become more apparent, forming rugae and sulci and resulting in a papillated topography. In the maxillary sinus, it is not uncommon to find rather large areas of hypertrophy and polyps, while other areas show

FIGURE 15.

Showing the terminal stages of fibrotic sinusitis with metaplasia of the epithelium, hyaline basement membrane, atrophy of the glands, fibrotic Tunica-Propria, sclerotic vessels, marked fibrous thickening of periosteum with irregular bony changes.

atrophy. This variety of pathological processes is particularly difficult to classify, because the tissue removed may be from a hypertrophic or atrophic area, and unless the source of tissue is

carefully correlated with the pathological processes involved these may be erroneously interpreted. The bony changes in this type are irregular. In some places there are osteoporosis and softening from absorption, while in others there are osteitis and exostosis. In many instances, in spite of the areas of atrophy, there is a general redundancy of fibrous tissue, and therefore the whole membrane appears thickened. The microscope reveals arthritis, phlebitis and lymphangitis, with perivascular involvement of the adjacent structures and the secondary changes in the tissue characteristic of both an atrophic and hypertrophic nature.

The elassification of chronic sinus diseases upon the vascular basis is supported therapeutically in the employment by rhinologists of drugs and measures which alter the blood supply to the mucous membrane of the nose and sinuses. The mucus membranes of these structures are more subject to vascular changes from intrinsic and extrinsic causes than any other similar surface in the body; also the physiological functions of these membranes have no analogy elsewhere. This is particularly true in relation to the amount of

blood which passes momentarily through this region, with frequent variations in the caliber of the blood vessels made necessary to adapt to every variation in the temperature, humidity and barometric pressure of the atmosphere. Therefore the slightest tissue alteration which affects the efficiency of the vascular structures to respond to these changes will certainly produce abnormal physiology in those tissues whose normal functions are primarily dependent upon the resiliency and contractility of the blood vessels and lymph channels.

Any dissertation on chronic infective diseases of the nasal accessory sinuses must necessarily be many-sided, because of the complexity and the distribution of the tissues under consideration; this vascular interpretation of sinusitis differs in certain respects from that presented in the literature. Our interpretation is given because to us it clarifies to some degree, the nature of the processes underlying the pathology and clinical course of the diseases; and is not given dogmatically or in any degree of finality, but in the spirit of discussion with the desire to stimulate further interest and investigation of the subject.

Discussion by Dr. David Robb: After a careful study of Doctor Eggston's paper, I feel that there is very little I can say in way of discussion. I feel that this paper is valuable because of the attention it calls to the importance of the rôle of blood and lymph vessels in the production of the polypi. These new growths are often lightly dismissed as the mere result of the effect of chronic inflammation, with no real thought as to the mechanism involved or as to what actually gives rise to them.

The paper also serves to differentiate the polypi of the sinuses from the true fibromata. The polypi apparently result from a passive type of con-

gestion rather than an active inflammatory hyperemia and thus can be classed as a mechanical type of tissue overgrowth rather than a neoplastic process. There has been a controversy as to whether or not these growths are genuine fibromata. Some pathologists still consider them as such, and this outline tends to make the line of demarcation between the two clear and definite.

The elassification offered by the author is simple and workable; and he is to be commended in that he clarified rather than confused the situation by refusing to introduce numerous new terms and complicated phrases in a classification based on pathological minutia.

MAXILLARY SINUSITIS—SYMPTOMOLOGY* By JOHN F. FAIRBAIRN, M.D., BUFFALO, N. Y.

I N a symposium of this kind, it is extremely difficult to avoid reaching beyond the limits of the subject assigned. However, I will attempt to enumerate the signs and symptoms of maxillary sinusitis, without undue reference to the pathology involved or the value of the symptoms in diagnosis, both of which will be presented as separate entities.

Pain is not a constant symptom. It occurs more frequently in the acute or acute exacerbation of

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

a chronic maxillary sinusitis. It varies in intensity through all the stages, from a mere uncomfortable sense of fullness or pressure in the upper jaw to the intense neuralgic type of pain resembling a tic douloureux. Because of its inconstant location, pain is not always a diagnostic symptom, as frequently the only pain complained of will be supra-orbital, no reference being made by the patient to the maxilla. In my experience, there is less tendency to periods of remission of pain in antral disease, that is, periodicity of pain is less marked than in inflamation of the other

sinuses. This symptom, pain, is usually relieved immediately either by spontaneous evacuation or

washing of the affected sinus.

Nasal blocking or stuffiness of the nose is an almost constant symptom, except in case of marked atrophic rhinitis. It is associated with more or less diffuse headache. As a rule there are periods of remission in which breathing will be comparatively free. On questioning the patient, it will be found, usually, that he notices relief following the evacuation of a large amount of mucous or muco-pus.

Disturbances of the sense f smell occur due to the blocking of the airway of the olfactory fissure. This may be due to congestion of the mucosa or

hyperplasia of the mucosa in chronic cases.

Consciousness of a foul odor, which may also be decidedly obnoxious to associates of the patient, is a symptom rarely found in other sinus infections, but frequently present in maxillary sinusitis, especially in maxillary sinusitis of dental origin. It is most marked when the patient sneezes, coughs or blows his nose.

While not a diagnostic symptom, excoriations of the alae or upper lip, especially in children should lead to consideration of the possibility of antral infection. I feel that it occurs more frequently in involvement of the antrum, because of the relatively greater amount of secretion from this sinus. I am not unmindful that this symptom is characteristic also of nasal diphtheria and for-

eign hody

It is remarkable to note the number of patients whose chief complaint is post-nasal discharge. They describe with great vividness the nausea attendant on the gagging and hawking necessary in the morning effort to clear the naso-pharynx. I consider this morning collection of pus or mucopus a very important symptom, though I believe it is more frequent in antral disease than in that of the other sinuses, first, because of the greater size of the antra and second, because of their tendency to drain when a person is lying on his back, for the accessory openings of the antra then have free play. It should be kept in mind, however, that over-indulgence in alcohol and tobacco frequently gives the same morning symptom.

The objective symptoms are external and intranasal. Swelling of the cheek may occur especially in antritis of dental origin, though I feel it is a rare symptom. Swelling is more frequently the result of infection of the alveolar process or a dental cyst. Palpation of the cheek may disclose a thickening of the periosteum of the canine fossa. Pressure over the canine fossa may elicit pain. Oedema of the lower lids, especially in children, is a symptom which should, at least, lead to investigation of the antrum.

Intra-nasally there are certain signs which are of great value. In acute cases particularly, there is always associated with the inflammation of the antrum, marked tumescence of the mucosa of the inferior turbinate. In chronic cases, due to the continued congestion, there may be true hyperplasia of the mucosa, not only of the inferior but also the lower portion of the middle. If anterior inspection shows pus flowing over the inferior turbinate or lying on the floor of the nose or if, posterior inspection discloses muco-pus coming over the inferior turbinate arising between it and the middle, it is a very significant indication of antral disease. Where large quantities of pus and mucous are found in the naso-pharynx or a condition of Pharyngitis Sicca exists, thought must be given to the antrum because of its size. At the same time it is well to remember that the same symptom occurs in involvement of other sinuses.

Nasal polyps arising about or coming through the opening of the antra and hyperplasia of the mucosa in that region are signs of chronic antral

disease.

In acute and acute exacerbations of chronic maxillary sinusitis there is usually some rise in temperature and an associated increase in pulse rate. In cases of chronic involvement there may be a slight daily rise in temperature. This symptom, however, is present more frequently in children. The leucocyte count is characteristic of infection and in the severe acute types shows a shift to the left.

A general symptom of importance is the marked mental depression so frequently associated with antral disease. In persons of unstable nervous temperament it may become a very serious melan-

cholia.

Having presented the signs and symptoms, I would add, that there are many cases of maxillary sinusitis, which unfortunately seem to run their course without the patients ever even suspecting or the physician having reason to recognize them. These are the cases that modern diagnostic methods are revealing and as a result we have reason to hope some cases of unexplained focal infection may be traced to their source.

Discussion: Dr. E. P. Hall, Syracuse, N. Y. The symptoms of maxillary sinusitis have been so thoroughly outlined that there remains little to say, unless to emphasize some of the important points. The essayist has divided the symptoms into subjective and objective; another classification that I like is reflex, functional and structural, and the reflex symptoms are most apt to lead us astray. The supra-orbital pain already mentioned

by the speaker should be emphasized as comprising almost half the cases, while many have generalized headache, without any reference to locality. Another reflex symptom which I have encountered is cough, non-productive and almost spasmodic in character. A case that impressed this on me was that of a young married woman who transilluminated normally, and in whom the X-ray picked the right maxillary as the offending sinus. Lavage

removed a large amount of muco-purulent material, with immediate relief of the distressing cough.

Of the functional symptoms, nasal blocking, profuse discharge and loss of resonance of the

voice are so obvious as not to require emphasizing. While the symptoms we class as structural, namely tenderness enternally, and swelling either externally or in the nose need only to be differentiated from alveolar trouble.

DIAGNOSIS OF MAXILLARY SINUSITIS*

By MARVIN F. JONES, M.D., NEW YORK, N. Y.

I FIND it most difficult to limit myself to the topic assigned to me. The diagnosis is inseparably a part of the symptomology of maxillary sinusitis.

My presentation will therefore consist of a description of routine and special examinations.

(I will use the lantern slides.)

Routine examination includes inspection of the nose, throat and larynx, first without medication. Following this procedure, alypine 30% and adrenalin 1-1000 is placed on a long pledget of cotton and the excess fluid removed. One of these is placed in each side of the nose and allowed to remain about five minutes. During this five-minute period the sinuses are transilluminated. The cotton is then removed and again the nose is inspected, the nasopharyngoscope being the last instrument used.

Since using the nasopharyngoscope routinely I have found it to be a most valuable aid. By introducing the instrument slowly, a good view is obtained of the nasal passage. Pus, which has been unnoticed by anterior rhinoscopy, is often seen with the scope. This is particularly true in the view of the nasopharynx. Posterior rhinoscopy is difficult and at times impossible. The view obtained is transient, except in the most favorable cases. Detailed examination of the entire field is not feasable. With the nasopharyngoscope one can examine the entire field in detail, leisurely and without discomfort to the patient.

In maxillary sinusitis pus may be seen flowing from the maxillary osteum, over the posterior tip of the inferior turbinate, along the lateral nasopharyngeal wall, around the eustachian orifice and down into the pharynx. Not uncommonly polypi may be seen emerging from the osteum. Hypertrophy or degeneration of tissue in the masopharyngeal area is an evidence of prolonged irritation resulting from sinus pathology.

I include the following under special examinations:

1---X-ray

2-X-ray with radiopaques

3—Antrascopy4—Aspiration

5—Lavage {Cytological Bacteriological

The x-ray is an aid to diagnosis and not of itself a diagnostic procedure. Poor radiographs and poor interpretations are worse than worthless, they are misleading. My patients are never subjected to the additional expense and trouble of having radiographs made unless there is a definite indication for making them. In other words, I do not order routine x-ray examinations.

Stereoscopic radiographs are always requested and these are taken in the lateral position. They are more informative than the picture without perspective. Three antero posterior flat plates are added to our lateral stereoscopic plates. Two of these are used for different angles through the antra.

We are revising our interpretation of radiographs because of information we have obtained through the use of radiopaques. This brings us to the second subject under special examinations,

i.e., radiopaques.

I have used radiopaques in my office for about three years. As experience broadens our knowledge we are constantly discovering new pictures and interpreting these pictures in terms of sinus pathology. The statement that a negative irrigation means a negative sinus is wrong. Not only do our radiopaques prove this, but cytological and bacteriological examination of the return flow also prove the statement to be incorrect.

Balmer showed that 76% of antrum washings which were objectively negative showed positive bacterial growths. Several investigations have substantiated the theory that normal antra are sterile.

We have seen radiographs of antra which showed extreme degrees of cloudiness, but were considered negative when irrigated and also apparently negative at operation. We have been puzzled by these findings.

The use of radiopaques has shown us that these cloudy pictures are caused by cedema of the mucus membrane lining the antrum cavity. On two occasions I have succeeded in penetrating the antrum wall with my trocar and aspirated fluid without injuring the lining membrane. On one occasion I removed the anterior wall and preserved the cedematous membrane. When this

^{*}Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., on May 25, 1932.

Given a case of maxillary sinusitis what shall we do to relieve the symptoms other than operative procedure? Many excellent results follow the simple use of cocaine either by applicator or tampons held in place for a short time in the inferior and middle meatus followed by ephedrine or adrenalin used as a spray or with applicators and These act to constrict swelling, allow drainage and relieve in many the pain so frequently complained of. Tampons of argyrol 25% to follow the above will be of value. measures are common office or bedside procedures for the attending doctor. The patient will get relief by using a warm saline spray or douche two or three times a day, during the intervals between calls.

The nasal mucous membrane is often very sensitive; use care in your medication. Some types of medication to certain membranes are very irritating and cause distinct pain. For the pain in all these sinus cases use codeine or the coal tar products, in some morphine is necessary.

An operative procedure frequently followed of puncturing the internal wall of the sinus with a Lichwitz or similar needle for better drainage or to wash out the sinus with warm saline is indicated in many cases. This can be done below anterior third of the inferior turbinate or under the middle turbinate near or about the normal ostium. My choice is the first procedure as it gives better drainage. In a few cases the wall is thick but even this can be overcome by using a chisel.

Mild suction is also of value in certain cases. If however, the discharge continues and with little change in amount or consistency believe it unwise to continue the above treatment over ten or twelve days if no marked improvement takes place. The case should now be considered an operative one and one of the many excellent operations decided on and followed. Time will not permit a discussion of these; they are all described in any standard text book; I will simply limit the operation procedure to what has been a successful one with the writer with, however, no lack of respect for the others.

In all cases of polypi, cyst or suspected tumor, foreign bodies, no time should be wasted. Consider surgically all these. In antrums filled with pus, and not seen until a considerable time has elapsed from the onset, operative procedure indicated at once.

First the usual intranasal operation that gives a good opening in the antrum nasal wall. For this under cocaine anaesthesia, a Halle, Coakley, Miles

or Story trocar can be used, followed by a rasp to enlarge the opening when many of these purulent cases will clear up by careful care and attention. My choice is the Caldwell-Luc operation for the radical operation. Have performed this under both local and general anaesthesia. In many a bilateral operation was necessary. The steps of the operation it would seem unnecessary to go over, but two things are important; make your opening large in the anterior wall. Portman of Bordeaux called my attention to the so-called four points. These he lays emphasis on and explores carefully the superior external, superior internal, near the angle of lower margin of the orbit and nasal wall. Here a septa or pockets will be found. These many times keep up trouble. The lower external and lower internal corner should be carefully explored for same reasons. opening in the nasal wall should be adequate and down to the floor if possible; save the nasal mucous membrane as much as possible but not the antrum. Polypi and old granulations can then be properly removed and the entire antrum inspected. Respect for these points will spell success in many an obstinate case.

One adjunct to this treatment is irrigation. I have used for some time instead of usual irrigation a DeVilbiss spray bottle with a curve tip that will enter the nasal or Caldwell-Luc opening. The air pressure needed for the above spray should be reduced to a minimum. It simplifies the irrigation causes less trouble and muss, it is easy to manipulate and not near as painful or annoying to the patient as the usual type of irrigation. Saline or boric solution used. Light packing advisable for short time. Do not allow the opening to close too early.

Change of climate very excellent in many of the cases. Constitutional treatment important as many of these follow grip, pneumonia, etc.

In all cases with a positive Wassermann approved treatment for this is necessary and no success will result if neglected.

Conclusions:—

Use every possible means to prevent these cases becoming chronic.

Make your openings large enough to give good drainage and make it easy to treat by irrigation, etc., with minimum of pain.

Proper light very important in operating. Don't put off operative work too long.

Have not attempted to go over any operative procedure where malignant conditions are found as they do not come I believe within the scope of a paper of this type.

Discussion: Dr. Austin G. Morris, Rochester, N. Y.—Dr. Sulzman has given a very thorough review of the treatment of maxillary sinusitis. and there is little of importance that I can add. I am impressed, however, that a note of conservatism

should be sounded in the treatment of this condition, and I believe cooperation with the pediatrician and internist is a very important factor in the recovery of our patients thus affected.

I am particularly conservative in the treatment

of children under twelve years of age, as I believe in this class of case, recovery is obtained by careful attention to drainage and ventilation of the nasal chambers by means of medication, proper hygiene, and attention to general health and treatment of constitutional symptoms. When it is necessary to resort to surgery, I believe the window operation in this class of case is usually all that is necessary.

In the treatment of the adult case, when irrigation has failed to bring proper results, and after careful diagnostic procedures have been used to ascertain the exact condition of the sinus cavity by x-ray, transillumination and injections of lipiodol, the window operation may be used with

Discussion: Dr. S. J. Parlato, Buffalo, N Y .-I wish to emphasize the part which allergy plays in the diagnosis and treatment of sinusitis. The allergic role has been mentioned several times during this meeting and it was particularly gratifying to me in listening to Dr. Jones's paper that he places considerable importance upon this question of allergy. It was Dean who stated that in all chronic sinusitis in children, the question of allergy must be considered before proper treatment can be outlined. After all, there is nothing in the practice of allergy that is conflicting with the usual practice of the Rhinologist. A consideration of protein hypersensitiveness serves to supplement our present day knowledge and guide us before too much or too radical surgery is done. Dr. Eggston gave us a splendid picture of the success if there is not too much swelling of the mucous membranes lining the antrum, or evidence of polypoid degeneration. In the more severe cases, the Caldwell-Luc operation is, in my judgment, the operation of choice. I wish to call attention at this time to a large group of cases in which the infection is not confined to the antrum of Highmore, but in the anterior group of sinuses, which may be diseased and draining into the antrum; the antrum in these cases acting as a reservoir for pus and secretion from the upper sinuses. In this group of cases, our attention should be directed to the sinuses primarily affected, and very little attention will be found necessary to the antrum itself.

pathological processes which occur in sinusitis. He spoke of extrinsic causes which induce these pathological changes. Among these factors one should consider that the inhalation of pollens, animal danders, emanations of caddis fly and such uncommon substances as glue or insecticides as well as the ingestion of foods and beverages can cause the edema of the mucous membrane of the sinuses, thus making it easy for bacterial invasion and resulting in repeated acute and then in chronic infections.

It is suggested that before a patient with a chronic nasal sinusitis be submitted to repeated or radical sinus operations, a search should be made for any protein hypersensitiveness such as taking a careful case history and making the necessary protein skin tests.

VALUE OF IMMUNE ADULT BLOOD IN THE TREATMENT OF MEASLES* By ALBERT D. KAISER, M.D., ROCHESTER, N. Y.

EASLES is not one of the serious diseases of childhood but nevertheless has a case fatality of 2 per cent. The largest number of deaths from measles occurs in children under two years of age, 55 per cent. After the third year, the number of deaths rapidly declines. Measles causes 2.4 per cent of all the deaths in children under 10 years of age and approximately 6 per cent. of all the deaths in children between one and three years of age. The 10,000 annual deaths from measles and its complications, as recorded in the registered area of the United States allow no optimism either on the part of the laity or on the part of the medical profession.

To combat the ravages of this disease many

Read at the Annual Meeting of the Medical Society of the State
of New York, at Buffalo, N. Y., May 25, 1932.

able minds of Europe and America have long been mobilized to work out a means of controlling this infection. It now seems certain that various mechanical methods of disinfection and quarantine can never control the disease clinically or epidemiologically. The trend of modern research on measles has assumed the line of biologic methods which include bacteriology, experimental inoculation in man and animals and the prophylactic and therapeutic application of these results of study.

It would be interesting to review the research work that sought to identify a specific bacterium as an etiological factor in measles and the numerous experimental inoculations attempted in man and animals. In view of the inconclusive results in this field, the clinician is concerned chiefly with the methods that

may be utilized in immunizing a child against measles or influencing the severity of the in-The most interesting and valuable contribution of modern research in measles is undoubtedly the discovery of a method of prophylaxis by means of measles convalescent serum. The fundamental principle of this procedure is, of course, a production of passive immunity with the antibodies formed in the blood of the patients who have recovered from the disease, a fact well established in diphtheria and tetanus. The first use of measles convalescent serum was recorded by Weisbecker in 1896. He published a detailed account of its use for therapeutic purpose using large amounts of serum at the beginning of the disease. His results were favorable so he suggested that it might be used as a preventive measure. Cenci was the first to use the convalescent serum for purposes of passive immunization. His work begun in 1901 was published in 1907. He prepared the serum from a child who was one of the first in the epidemic to have the disease and injected this serum into a number of children but failed to inject other children of the same families who served as controls. He observed that measles was prevented in the protected children but in a later epidemic they contracted the disease indicating that the passive immunity conferred by convalescent serum is of short duration.

On account of the short duration of passive immunity conferred by an injection of convalescent serum a method of inducing a more permanent immunity was sought. The first attempt to obtain an active immunity was made by Herman, of New York, who in 1915 endeavored to induce a mild form of the disease in young infants. This was done by inoculating the mucous membrane of the nostrils with the diluted secretions from measles patients. Following the reaction or perhaps the attack of attenuated measles, the child was found to be immune when exposed to measles at a later date. This procedure, however successful, could never be applied in a general way for measles prophylaxis.

The beneficial use of measles convalescent serum was recognized after the successful results published by Park and Zingher in 1916 and two French physicians, Nicolle and Conseil, in 1918. The most intensive studies were made by Degkwitz in 1920-1922, published in his reports of more than 1,000 cases treated with convalescent serum. His results were on the whole quite favorable in that if the disease was not prevented in some, it was lessened in its severity. Among his own series, 85 per cent showed complete protection. His most important contribution to the subject was the recognition that when convalescent

serum was not available, the serum of adults with a positive history of measles could be substituted. Haas and Blum in 1926 reported the successful application of measles convalescent blood to institutional children. Reference must be made also to use of measles antitoxin developed by Tunnicliff and Ferry. Success at prophylaxis has been reported with these animal sera.

In spite of the statement made by Degkwitz in 1922, practically no attempt was made to use immune whole blood of adults for the development of passive immunity until recently, Reference must be made to the few published results on the use of immune adult blood either for prophylactic purpose or for producing an attenuated form of measles. Barenberg, Lewis and Messer reported 64 per cent of the children benefited who received immune adult whole blood and 96 per cent benefited who received 6 c.c. convalescent measles serum. Morales and Mandry carried on rather extensive studies in San Juan, Porto Rico, and reported in 1930 their results with immune adult serum and compared its value with convalescent serum. They found that 85 per cent of 120 children immunized with convalescent serum were completely protected, while 80 per cent of 132 children immunized with 20 to 40 c.c. immune adult serum were completely protected. When doses of 10 and 15 c.c. of adult serum were given, complete protection was offered to less than 50 per cent immunized, but the others developed the disease in an attenuated or mild form. Not all reports on immunization are favorable. Blaumer and Goldstein reported unfavorable results with immune adult blood in 117 susceptible children.

Owing to the difficulty of getting convalescent serum and the uncertainty of immune goat serum, more attention has been given recently to utilizing immune adult blood, which in private practice usually means parental blood. Such blood is always available, it involves no expense and the objection of using strangers' blood is removed. During the recent epidemic of measles that began in Rochester, May, 1931, ample opportunity has been given to observe the value of immune adult whole blood as a means of preventing or modifying measles.

It was apparent from the experience of other observers, as shown in Chart 1, that small amounts of immune adult blood would probably prevent measles in very few cases. Inasmuch as the cases treated were all in private homes it seemed desirable to strive for attenuated cases rather than complete protection. In the presence of a city-wide epidemic, protection that would last only three to six

weeks was not as important as a permanent immunity following an attack of modified measles. With this in view, relatively small doses of whole blood were injected

This study is based on a series of 214 children who presumably had a definite exposure to an active case of measles. An exposure as described by the parent does not always constitute a true exposure. In order to interpret the results more accurately the treated children were divided into two groups, those having family exposures, which are usually quite definite, and those who have outside ex-

posures such as with neighbors or school mates. Owing to the marked infectivity of measles it has been shown that approximately 80 per cent of family exposures result in the development of measles. Of the 214 children injected, 162 were in families where an active case of measles existed. Fifty-two children were exposed less definitely and therefore are grouped separately.

Children were injected between the third and seventh day after exposure. The fourth day was generally selected. In seven instances blood was given after the tenth day because exposures were not computed properly. The amount of blood injected was usually 10 c.c. In a few instances 15 c.c. was given, but never less than 10 c.c. In practically all instances the blood was injected into the gluteal muscles. Reactions developed in five children. They occurred on the fifth day and were characterized with swelling, local tenderness and fever. All recovered without any great discomfort. Where parental blood was utilized no Wasserman tests were made.

adult blood will completely protect only a small percentage of children against measles if they are definitely exposed.

Among the 162 treated children with known family exposures 75.5 per cent developed measles, while only 25 per cent of the 52 who had uncertain exposures contracted the disease. The effect of the blood injection could be easily evaluated in the 135 children who developed measles. One hundred and seventeen had what has been termed modified or

In seeking to interpret the effect of the blood injections in these children three kinds of results were noted. There was either complete protection against an attack of measles, a modified or attenuated attack of measles or an average uninfluenced attack of measles. Complete protection was not anticipated in a high percentage of the children, due to the small amount of blood injected. Among the 162 children, as shown on Chart 2, who had family exposures, 40, or 24.5 per cent, failed to develop the disease. It cannot be assumed that 24.5 per cent were passively immunized as a result of the injection of 10 c.c. of blood, for it is known in control studies, especially those of Morales and Mandry, that about 20 per cent of children with like exposures escape the disease either through failure to be infected or because of a natural immunity. Among the 52 who were reported to have had exposures other than those from a member of the family, 39, or 75 per cent, failed to develop measles. This high percentage of complete protection was undoubtedly due to the absence of a definite exposure. It seems probable, therefore, that the injection of 10 c.c. immune

attenuated measles and 17 had what might be considered an average attack of measles and only one case of severe measles developed among the children who were treated with whole blood. An attenuated or modified attack of measles presents a clinical picture much less severe than an average case; the prodromal symptoms are either absent entirely or so mild that they are hardly recognized; the cough is usually absent, the fever rarely over 102° F., or if higher, of short duration, the exanthem is atypical and the throat symptoms absent or less severe. The period of disability is usually three of four days instead of seven or eight days.

Failure of the blood injection to alter the course of the infection was noted in only 8.3 per cent of the children treated. These 18 children developed measles that was apparently no different from an average case. A number of the failures could be accounted for by the late injection of blood due to miscalculation on the time of exposure. Even in the so-called failures the attack of measles was in no instance worse than an average case.

It is well known that in an epidemic of

measles many mild cases occur. This is particularly true in the disease outside of institutions. One wonders, therefore, if many of these attenuated attacks might not have occurred even without the immune blood injection. The interpretation of a mild, average or severe case depends somewhat upon the observers. In order to appraise the value of the blood injection in a more tangible way, 100 children with measles treated with 10 c.c. immune adult blood were compared with 100 children in the same families who likewise had the disease but were not treated with blood. Chart 3 describes the results in this comparative study. The degree of measles was noted by the same observer among the 200 children of 100 different families. In each family two cases occurred; the first case usually was not treated and the exposed child was given 10 e.c. immune adult blood. It will be noted in the chart that the treated children were more likely to be the younger children under five years of age. It is in this age group that measles is most likely to be associated with sequelae. Among the 100 untreated children, 84 had an average attack of measles and 16 a severe attack. There were no mild or attenuated forms among these cases. The complications existed in fourteen children, consisting of pneumonia, bronchitis, otitis media and cervical adenitis. Only sixteen of these children were below five years of age. Among the 100 blood treated children, 87 had a modified form of measles, 12 an average attack and one a severe case. Similar complications existed in only two children. Seventy-six of the children in this group were below five years of age. Whatever uncertainty may exist in the interpretation of the degree of severity in an uncomplicated attack of measles, the sequelae or complications cannot be misjudged. In the untreated cases, 14 different children presented

serious complications, while among the treated only two children presented similar complications.

The value of injecting 10 c.c. immune adult blood to children exposed to measles is demonstrable in the modification of the disease. A mild case can usually be anticipated and the chances for complications are decidedly less-There is very little evidence at hand from this study to show that a passive immunity is obtained in many children. institutional and hospital practice protection against measles may be desirable in order to check the spread of the disease, but in family or private practice more can be accomplished by assuring the patient an attenuated attack with permanent immunity than a passive immunity of short duration which may be lost when another exposure comes.

Discussion: Dr. Camille Kereszturi, New York, N. Y.:

During the past eleven months, we have been carrying out a piece of research work in the Fifth Avenue Hospital, under the supervision of Dr. Park, on the prevention of common contagious diseases in our children's wards. We found in previous years that in spite of the rigid quarantine system of the Department of Health of New York City, we had numerous outbreaks of contagious diseases in our wards. The wards were therefore unavailable for admission for about one-third of the year.

Since July, 1931, we obtained permission from the Health Commissioner to keep our wards open irrespective of different outbreaks. Our procedure is as follows: If a case of communicable disease is diagnosed in our wards, we remove the patient, do not quarantine the ward, but divide the exposed children in two groups: 1. Those who have an acquired or natural immunity to the disease in question. 2. Those who are susceptible as demonstrated either by the Schick and Dick tests or by negative past history of diseases of which we have no susceptibility tests.

To half of the second group was given 5-7 c.c. homologous convalescent serum intra-

Conclusions

- 1. During a measles epidemic the use of immune adult whole blood may be effectively used in assuring that the patient will have an attenuated attack which confers a permanent immunity.
- 2. The use of 10 c.c. whole blood has been found sufficient to modify an attack of measles and materially reduce the incidence of complications.
- 3. The use of 10 c.c. immune whole blood will not completely protect children who have been definitely exposed to measles. Much larger amounts are necessary for complete protection.
- 4. The use of immune whole blood, usually parental, is simple, safe, inexpensive and effective in the treatment of measles, especially in private homes.

muscularly. The other half of the susceptibles

were kept as controls.

Among 643 admissions in the past eleven months, we had sixteen outbreaks of one of the following diseases: Pertussis, measles, German measles and scarlet fever. According to the present quarantine rules of the city, this would have meant nineteen weeks of closed hospital doors. We were exempt from quarantine and still did not see any second case of any of these communicable diseases but measles. In two outbreaks of measles, 12 per cent of the immunized and 41 per cent of the control children developed the disease. However, the immunized ones had a very much milder, modified form of measles.

Therefore, we are planning to carry out this research with the aim of finding out:

- 1. Whether the present rigid quarantine system is necessary.
- 2. How much good can be obtained in prophylaxis by the use of convalescent serum against not only measles, but pertussis, chickenpox, scarlet fever, mumps and German measles.

3. What is the proper dosage of serum for

prophylaxis.

4. When is the ideal time to bleed convalescent patients in order to obtain the most potent serum.

CONDUCTIVE ANESTHESIA FOR THE ELECTROSURGICAL REMOVAL OF TONSILS

By EDGAR R. MAILLARD, MD, NEW YORK, N. Y

A NYONE who is forced to have his tonsils removed because of some local or general disturbance is today concerned with the choice of a method of surgical removal. If one may assume that a decision is mide in favor of the electrosurgical extripation invariably the first question asked is whether the method is, a painless one. On referring to the literature on the subject it would be very difficult to make a satisfactory reply because of the conflicting opinions in connection with the question of pain.

After several years of persistent effort, it has been possible to develop a technic' which results in the complete removal of tonsils. One is markedly impressed, however, with the fact that the treatments are not entirely free from pain, requiring an effort on the part of the patient to continue with the subsequent treatments. It was realized that if complete anesthesia of the tonsils could be effected, the patient would be spared the anxiety and fear which are experienced with each With this in mind various kinds of anestheties were used chiefly in the form of topical applications, since the injection of fluid into the tonsillar tissues is not advisable of the topical anestheties produced a greater degree of anesthesia than others, but at no time was the anesthesia complete although it was possible to administer the treatments

A careful study of the anatomy and nerve supply of the tonsil and adjacent structures suggested the idea of attempting a conductive anesthesia. Varying amounts of a 2% solution of procaine with epinephrine (1-2500) were injected at different points in the region of the tonsils. The results were very gratifying at times and quite discouraging at other times. Finally it was noted that an injection made in the region of the superior fossa of the tonsils infiltrating behind the capsule to a depth of about one inche caused complete anesthesia of the tonsil, soft palate and base of the tongue within five to ten minutes on the injected side. The loss of sensa-

tion in these regions is apparently due to an infiltration of the branches of the glossophiaryngeal nerve which supply this area. It was possible to repeat this condition at each weekly visit on the same patient for a series of treatments. I have given approximately fifty injections and have obtained the desired anesthesia in all instances. The post operative results have been the same as with the use of the various topical anesthetics.

The first indication of anesthesia is usually the presence of a nasal intonation of the patient's speech. One of the reactions noted in patients lias been the reguirgitation of liquid through the nasal orifices when attempting to drink water. This may be attributed to a disturbance of the normal reflex of swallowing caused by the loss of sensation. There were also a few instances of increased lacrymation and feeling of warmth on the side of the face due to involvement of the sympathetic nerve fibres. All of these reactions were of short duration and not alarming in character.

SUMMARY

A conductive anesthesia has been developed that produces loss of sensation in the region of the tonsil, soft palate and base of the tongue. This makes the electrosurgical extirpation of tonsils a painless procedure, consequently it allows for better cooperation on the part of the patient and makes the complete removal more assured. For this reason also the number of treatments is reduced to the minimum. It is exceptionally valuable in the removal of tonsillar remains which is usually more painful than the first treatments in the elimination of a whole tonsil. There are no apparent dangers and the administration is well tolerated by the patient

Conclusion

The electrosurgical removal of tonsils may now be accomplished without any pain whitever to the patient. This has been made possible by the introduction of a conductive anesthesia.

PRESIDENTS, DISTRICT BRANCHES

Third District—CLARK G. ROSSMAN, M.D	—EOWARD R. EVANS, M.D
--------------------------------------	-----------------------

SECTION OFFICERS

Medicine—Alfreo M. Weod, M.D., Chairman, Clitton Springs; Frank Bethel Cross, M.D., Sccretary, Brooklyn.
Surgery—Floyo S. Winslow, M.D., Chairman, Rochester; Eogar A. Vander Veer, M.D., Sccretary, Alhany.
Obstetries and Gynecology—Milton G. Potter, M.D., Chairman, Buffalo; Howard C. Taylor, Jr., M.D., Sccretary, New York.
Pediatrics—Adolph G. De Sanctis, M.D., Chairman, New York; George C. Sincerdeaux, M.D., Vice-Chairman, Auburn.
Ophthalmology and Oto-Laryngology—Frank M. Sulzman, M.D., Chairman, Troy; Webb W. Weers, M.D., Sccretary, New York.
Public Health, Hygiene and Sanitation—Stanley W. Sayer, M.D., Chairman, Gouverneur; Walter A. Leonaro, M.D., Sccretary, Cam-Liville

Dernatology and Psychiatry—Leon H. Cornwall, M.D., Chairman, New York; John L. Eckel, M.D., Sceretary, Bustalo.

Dernatology and Syphilology—George M. Fisher, M.D., Chairman, Utica: Frank C. Combes, M.D., Sceretary, New York.

Radiology—Joseph M. Steiner, M.D., Chairman, New York; Donalo S. Childs, M.D., Vice-Chairman, Syracuse; Leo P. Larkin, M.D.,

Secretary, Ithaca.

LEGAL

Office at 15 Park Place, New York. Telephone, BArclay 7-5550

Counsel—Lorenz J. Brosnan, Esq. Attorney—Thomas H. Clearwater, Esq.

AUTHORIZED INDEMNITY REPRESENTATIVE Harry F. Wanvig, 70 Pine Street, New York

Executive Officer—Joseph S. Lawrencz, M.D., 100 State Street, Albany. Telephone, MAin 4-4214. For list of officers of County Medical Societies, see this issue, advertising page xxii.

THE ANNUAL MEETING IN RETROSPECT

The one hundred and twenty-seventh annual meeting of the Medical Society of the State of New York has become a record of achievements, and a memory of anticipations fulfilled. The meeting was a parade of the standing army of the medical profession demonstrating its preparedness to combat the forces of disease and death.

While the meeting preserved the ancient tactics which require each soldier to fight in the front line of battle, it also sought to enlist every citizen in the service of health by its radio broadcasts, its session open to the public, and its press publicity service. The meeting brought gratification to those who planned it, and satisfaction to those who attended it.

DR. FREDERICK H. FLAHERTY

To be chosen President of the Medical Society of the State of New York is a promotion to a wider field of activity given to a physician who has acquired experience, knowledge, and judgment in advancing through the services in his county medical society, and the hospitals and social service organizations.

The President is the exemplification of the medical profession during his year of office, and represents the ideals of the practice of medicine as he speaks before numerous organizations both medical and social. The members of the Medical Society of the State of New York have always exercised keen discernment and good judgment as they have surveyed the records of their presidential candidates, and assumed that those who have been faithful and efficient in the county societies and on State committees will carry on their good work in the highest office. The wisdom of this method of choice is demonstrated by the services which presidents give as chairmen and members of committees after they have served their terms as president. The honor and fame which the office has brought to the presidents have been incidental to their opportunities for constructive service.

These are the thoughts which the members of the Medical Society of the State of New York have in mind as they greet their new president, Dr. Frederick H. Flaherty. They are confident that in his new office he will continue the same efficient leadership that he has demonstrated in the medical circles of Syracuse.

Portrast by Carson Robert Draucker

FREDERICK H. FLAHERTS, M.D., President of the Medical Society of the State of New York.

COSTS OF MEDICAL CARE

A Special Committee of the Medical Society of the State of New York, appointed to consider the final report of the national committee on the Costs of Medical Care, expressed its opinion to the House of Delegates on the evening of Monday, April 3, 1933, in the report which is printed on page 499 of this Journal, and which the House adopted unanimously. The impression gained when listening to the reading of the report was that it was fair and judicial; and that impression has been confirmed by a careful study of the report, and a comparison of it with the report of the national committee.

Four months have gone by since the national report was made public, as was told in this Journal of December 15, 1932, page 1438; and during that time the medical journals of the State societies have printed extensive opinions varying

from violent condemnation to fulsome praise. The leaders of the Medical Society of the State of New York wisely decided that the opinion of the medical profession of the State should not be expressed until members had given consideration to every phase of the national report. A Special Committee of the Society was appointed to formulate that opinion, and make its report to the House of Delegates. This Committee has had the benefit of information regarding the background of the work of the national committee and the influences which led the Committee to formulate five reports insead of one united report. The report of the Special Committee is concerned principally with that part of the report of the National Committee called the "Majority" report.

A reviewer of the majority report may take either one of two attitudes:

- 1. He may take up the report, paragraph by paragraph, and consider each item separately, as one looks at the individual trees of a forest.
- 2. He may look at the report as a whole, as one would consider a forest in its general phases, such as its kind of trees, its location, and its likelihood of preservation and increase.

The State Committee has given careful consideration to the broader phases of the majority report and the trends of its recommendations.

In order to understand the comments of the Special Committee, it will be well to recall that the majority report contains five specific recommendations which are set forth in Chapter Five of the report, on pages 104 to 144 of the printed volume. These five recommendations are as follows:

- 1. Group practice to be adopted by physicians, page 109.
- 2. The extension of public health services, especially health departments, page 118.
- 3. Sickness insurance to be taken out by patients, on a basis that is either voluntary or compulsory, page 120.
- 4. Coordinating agencies, local, state, and national, to be formed to suggest the standards and methods of a complete medical service, page 134.
- 5. Medical education of physicians, dentists, pharmacists, nurses, nursing attendants, midwives, and administrators to be promoted, page 138.

These five recommendations of the national committee, and the form and manner of their presentation, must be kept in mind while reading the opinion of the New York State Committee expressed in its report to the House of Delegates. That report very properly takes into consideration the attitude of the members making the majority report, as well as the content of their report. It also calls attention to the silence of the national committee on the work of medical societies throughout New York State and the nation in initiating and demonstrating the value of many forms of medical service that are advocated in the Majority report of the national committee, some of which are found to be impractical.

The State Committee also calls attention to the need of considering the quality as well as the quantity of medical service; and to the fallacy of the belief that the people will accept only the best medical service. The same temperaments which lead men to neglect their financial and educational affairs will also lead them to neglect their health. As a matter of fact, men generally care for their property far better than they do for their health.

The Special Committee devotes the second half

of its report to seven recommendations, which are to be compared with the five recommendations of the National Committee. The recommendations of the State Committee are along the following lines:

- 1. Provisions for medical service to the indigent by methods to be evolved by the County Medical Societies.
- 2. The rational distribution and proper zoning of hospitals which care for the poor, with provisions for payment of attending physicians by the community for services rendered to the poor.
- 3. A system of insurance to provide for hospital charges, but not medical fees, to be developed in communities where practicable.
- 4. Disabled veterans to be treated in civilian hospitals and only for conditions incurred in the service, except that the Government continue the care of neuropsychic and tuberculosis cases of all classifications.
- 5. Wherever Workmen's Compensation cases are admitted to municipality owned hospitals, the medical fees to be paid to the attending Surgeon.
- 6. The care of crippled children should continue under the direction of the State Board of Health, but local physicians should be employed so far as possible.

7. The adoption of the principles of the Geib-Vaughn-Detroit Plan, whereby the Departments of Health utilize the services of family Doctors in place of public clinics.

The last recommendation conforms to the general principle announced in the first half of the report,—that the fundamental basis of medical service in every instance is the preservation of the contact of an individual physician with an individual patient. The report agrees with the common opinion of physicians that neither group practice nor sickness insurance is consistent with a high quality of medical service.

The whole report confirms the opinion expressed in its opening paragraph: "The Medical Society of the State of New York is the competent body to suggest measures and remedies for

medical services in this State."

The truth of this quotation has been amply demonstrated by the great progress in the civic and administrative forms of medical practice achieved by the medical societies of the nation, the states, and the counties during the last decade. Concrete evidence of that progress is the fact that the list of those activities recorded in the New York State Journal of Medicine in each year now fills six pages of the annual index.

MEDICAL PROGRESS

Do Cancer Houses Exist?-Chaton takes issue with certain French authors (Lumière and Vigne) who have recently asserted that there are no grounds for the belief that cancer houses exist, and that chance alone is responsible for the unusual numbers of cancer cases observed in certain houses. He denies that the rôle played by chance is demonstrated by the fact that the curves of statistical data coincide with those given by the calculation of probabilities. The alleged dissimilarity of "the primary factors in cancerization," which are held by these authors to be the soil, parasites, fauna, flora, water supply, etc., in Paris and Lyons, where the demographic curves are in agreement, is not a fact. On the contrary, in all great cities the pathogenic agents in the soil, water, dust, air, foodstuffs, etc., are exactly the same (Eberth's bacillus, streptococcus, staphylococcus, bacillus of tetanus, diphtheria, etc.). Hence the statistical method can prove nothing either for or against the cancer house. It is quite evident that in the most crowded houses, where the greatest numbers of tenants are to be found, there would normally be the greatest number of cases of cancer, of births, deaths, or other physiological and pathological phenomena, since a parallelism of this kind would naturally exist. curves were to be constructed for the numbers of cases of tuberculosis and syphilis in Lyons, after a house to house canvass, it is certain that they would be exactly similar to those erected for cancer or for births; yet tuberculosis and syphilis are known to have biologically determining causes of a very precise nature. This is only the secondary aspect of the question of etiology. But in the study of cancer houses it is not the indirect causes that we desire to know, but the determining and efficient cause: and there is one that is not governed by chance. This cause will not be found by drawing up statistics, but by observing particular cases from all angles, and, with reference to etiology, by a study of the environment of the patients, that is, of places or houses where an abnormal number of cancer cases have been observed. There is nothing surprising in the fact that mathematicians with the calculation of probabilities bring us to no positive results. Their proper field is that of inert science, such as physics and chemistry. In medicine they cannot intervene usefully except in very rare cases. They may amplify a principle, but they will never discover one. So far as cancer houses are concerned, it seems still more manifestly premature, at a time when mortality statistics are non-existent or insufficient with reference to a disease the declaration of which is not compulsory for the physician, to hope to reach any de-

pendable conclusion from a calculation which at present must rest on foundations that are certainly incomplete if they are not actually erroncous.—Bulletin de l'Académie de médecine, February 7, 1933.

The Doubtful Clinical Usefulness of Lederer's Cancer Reaction .- The failure of purely clinical methods to make an early diagnosis of cancer, especially of the internal organs, and the long and complicated nature of the current laboratory procedures proposed for this end led Zwerg and H. J. Lauber to make a trial of Lederer's method of colloidochemical examination of the scrum of cancer suspects. This method claims to be able to diagnose cancer within 48 hours without any special technical difficulties. Lederer thought that it would be more easily possible to recognize the constitution of the intermediate products of metabolism in the blood of cancer patients by their colloid properties than by their purely chemical constitution. He therefore examined the scrums with reference to their protective action upon suspensoids. In view of the lesser content in protein and the greater degree of acidity of the blood of cancer subjects, the result in the suspensoids would be that the blood of a cancerous individual has less protective power against flocculation than that of a healthy subject. He called a solution "protected" if it was still clear after 48 hours, but no longer "protected" if it showed a slight clouding; and he claimed that with a Berlin blue solution as a suspensoid and a saturated saline solution as an electrolyte, he obtained a positive finding in nearly 80 per cent of cancer patients. Zwerg and Lauber accordingly tried this method of diagnosis in 33 cases of clinically and histologically proved cancer, in 9 that were known not to be cancer, and in 2 doubtful cases. Lederer had termed as the "protection number" (Schutzzahl) the number of cubic centimeters of serum in that solution, which is just protected; he found this to be 0.11 or over in cancer subjects, and 0.10 or less in healthy persons. Between 0.10 and 0.11 the case is suspicious of cancer. The authors found at once in their first examinations that they never obtained so high a protection number as Lederer for a cancer, and they accordingly modified their method to the extent that they let themselves be guided not by the protection number but by the number of flocculated tubes. While their results were for a while somewhat contradictory, they found that later their findings agreed on the whole with those of Lederer, in that they obtained a positive result exclusively with cancer patients, while the negative result did not unconditionally exclude

cancer, but was found in about 30 per cent of cases known to be cancer. At this period they felt justified in recommending the wider use of the method, but they have more recently been having the experience that they obtain no positive results at all in either cancerous or noncancerous patients, notwithstanding they use a Berlin blue solution that is above suspicion, furnished by Lederer himself, and prolong their observations over 4-5 days in the hope of obtaining flocculation. In over 50 per cent of cases among their recent material they have had no clouding, while in the remainder they have had flocculation in only one or at most two tubes, which according to both their own and Lederer's standard had to be considered negative. are therefore compelled to regard the Lederer reaction as unreliable on the basis of their own observations.-Deutsche medizinische Wochenschrift, February 24, 1933.

Treatment of Nonvalvular Heart Disease of Middle and Old Age.—Henry Jackson writing in the New England Journal of Medicine, March 16, 1932, ccviii, 11, emphasizes the importance of the myocardium in diseases of the heart and states that a study of his cardiac cases shows that fully 75 per cent of them were not due directly to valvular disease. Clinically the difficulties of the heart of old age are apparent when the heart muscle has been impaired by overwork, by strain, often without the concurrence of any severe acute process and very often without a strain dependent upon high blood pressure. It is in such conditions that the electrocardiogram gives the most help. It explains auricular fibrillation, premature contractions and sinus arrhythmia, all questions of much importance from the clinical as well as the scientific point of view. Sinus arrhythmia and premature contractions become of importance to the individual only when the myocardium fails. There is no specific treatment of avail for premature contractions, though small doses of bromides may be given to patients who are particularly sensitive to the disordered action of the heart. Digitalis is of no avail nor is it indicated. The prevention of nonvalvular heart disease in middle and old age is of more importance than its treat-As men grow older they should avoid excess of muscular exertion, and they must not think that they are as strong as they ever were. It might be of advantage to the business world if men were obliged to cut down their activities at the age of sixty-two or sixty-five years, though in the individual case such an age is often too young. The myocardial heart of old age does not differ essentially from any other form of muscular heart failure. First and foremost, warn against all strain of the heart, as in running, walking up hill, etc., but continue mild exercise as in walking on the level and the "daily dozen" in homeopathic doses. The heart muscle must be exercised to keep it in proper condition. Suitable cases are helped by graded massage and perhaps by the baths at the various heart resorts. An important factor is the avoidance of too much food. This is more important than the moderate use of alcohol and tobacco. Jackson does not like the term or the method known as "digitalization." In chronic heart disturbance associated with the failing heart of old age the dose is one or two grains of powdered digitalis given every day, omitting the dose one day a week, a day when all strain must be avoided. Nitroglycerin is often of value as a preventive before any collapse occurs. Codeine is of value, but it is very doubtful whether strychnine is useful execept for the suggestion to the patient that one is giving something to help a hard situation.

Dyskinesia of the Biliary Tract (Cholepathia spastica) and Surgery.—Modern research, say V. Schmeiden and H. Niessen, writing in the Münchener medizinische Wochenschrift of February 17, 1933, has learned to recognize the extrahepatic biliary system as a functional unit, that is to say, the gall-bladder and the bile-ducts down to their anastomosis with the duodenum. It has been shown that there are many cases of biliary colic that are not due to mechanical obstructions but to disturbances of innervationcases that present the picture of pseudocholelithiasis. The chief seat of these disturbances is in the sphincter of Oddi, where a spasm of the motor nerves may arise under certain conditions, which results in obstruction of outflow of bile; this in turn causes a distention in the entire system of bile-ducts, which produces a typical clinical picture due to the ineffectual peristalsis of the gallbladder and bile ducts exerted against the closed sphincter. The colic-like pains without stone, icterus or fever, are due to an intermittent stasis in the extrahepatic bile-ducts. For surgery to enter the thankless field of these neuroses seemed at first unjustifiable. Certainly modern investigators are right in warning against reckless intervention in dyskinesia of the biliary tract. Modern knowledge must discountenance the universal use of cholecystectomy when these symptoms appear. There are, however, other surgical procedures which may come up for consideration: (1) The operative stretching of the sphincter of Oddi by cautious use of bougies, with strict avoidance of brusque or rough handling, which might result in cicatrices and recidives. (2) Derivation procedures to divert the outflow of bile around the sphincter, such as the joining of the common duct to the duodenum, or making an anastomosis between the top of the gall-bladder and the intestinal canal (stomach or duodenum). Attempts to relieve the spasm by cutting the nerves have not produced practical results. The placing of the indications for treatment of dyskinesia of the bileducts might perhaps be compared with that for

round ulcer of the stomach or duodenum, where the failure of conservative measures to bring relief points the way to the employment of surgery without delay. In cases where diagnosis is doubtful, exploratory laparotony is advisable. When the neurotic-functional nature of the pain has been demonstrated, medical means should first be tried. If, however, these measures fail, one should not hesitate to have recourse to one or other of the operations recommended above.

Glucose-Insulin Administration in Prolonged Narcosis.—J. H. Quastel and R. Ström-Olsen, writing in The Lancet, March 4, 1933, cexxiv, 5714, point out the fact that narcotic treatment in certain types of mental disease has been interfered with by the knowledge that prolonged narcosis is often accompanied by toxic symptoms. In the Cardiff City Mental Hospital about 50 cases have been treated with somnifaine during the past two years, with extremely encouraging results except for toxic symptoms. Laboratory investigations were carried out on the mode of action of narcotics. The results, briefly, were: (1) All narcotics have the property of inhibiting specifically, at low concentrations, the oxidation by the brain of substances important in carbohydrate metabolism, viz., glucose, lactic acid, and pyruvic acid; (2) of narcotics belonging to the same chemical type, those with the greater narcotic activity have the greater inhibitive action on brain oxidations. A frequent accompaniment of prolonged narcosis is the development of ketonuria. It was found that the simultaneous administration of glucose and insulin to narcotized animals brought about a decrease in toxicity of the narcotic.

This work led to a consideration of the possibility of administering insulin and glucose to patients undergoing narcotic treatment. group of 20 patients 2 c.c. of somnifaine was administered intramuscularly two to four times in twenty-four hours. As soon as definite ketonuria appeared 5 to 15 units of insulin were administered simultaneously with the next intramuscular injection of the narcotic. With each insulin injection the patient received by mouth 50 grams of glucose in water or milk. These doses were found to be sufficient to avoid hypoglycemia. The immediate result of the insulin-glucose modification of the narcotic treatment was the entire disappearance of ketonuria within forty-eight hours, and the patient showed no ketonuria during the remainder of the course of narcotic treatment which lasted from fourteen to sixteen days. It was also noted that cyanosis, alarming drowsiness and vomiting partially or entirely disappeared with this treatment. Though the number of patients who received the insulin-glucose is small, the results have been so satisfactory that the authors feel justified in publishing this preliminary report.

Mineral-Free Water Therapy.-The medical profession, says Karl Glaessner, which has from time untold been interested in the detoxication of the body, has gravely neglected one single field of treatment, namely that of internal hydrotherapy. The most important regulator of metabolism is water: intake and outgo of water must balance one another. Most attempts to study the water metabolism have been conducted with ordinary drinking water or the so-called mineral waters. Not until 25 years ago was any attempt made to test the effect of so-called distilled water which To those who introcontains no mineral salts. duced such studies it was evident that with the aid of an entirely salt-free or salt-poor substratum very different effects upon diuresis and flushing out of the tissues must be obtained than if the fluids introduced were practically the same in their salt and organic content as the body fluids themselves. Three general sources of energy are to be differentiated with reference to water movement: (1) the purely hydrodynamic, (2) the osmotic, and (3) the electric. Water that is in colloidal combination is dependent on the influences of the electrolytes and the actual tissue reaction. In this connection the alternate action of hemodynamic and colloido-osmotie pressure is of significance. Hence it is clear that water without electrolytes and without salts will produce a very different effect from water containing salts and acids. By means of electro-osmotic and heat distillation the so-called hyperdistillate has been obtained, which is absolutely salt free and acid free, contains only a very small amount of gases, and these, harmless, and has an osmotic value of pH7, so that it represents the purest water that has ever been manufactured. It is useful both as a prophylactic in a state of health, and also in a long series of affections including those of the kidney and urinary tract, the liver and biliary apparatus, and in those processes that enter into high blood pressurc; also in migraine, Menière's discase, affections of the joints (gout), and of the tongue (leucoplakia). In kidney affections the water is given in amounts of 1-11/2 liters per day for 10 days in the month, followed by a pause of 3 weeks, after which the same is repeated; so that in the course of a year the water is used for 4 months altogether. In gallstones the same method is used, but in combination with a suitable cholagogue, preferably glycocholate of sodium in doses of 0.2 gm. 3-5 times daily. Some patients are entirely free from atttacks during the water treatment. In cases accompanied by chronic gastric catarrh Glaessner spaces the treatment in such a way that in the course of 6 months the water is given for 3 periods of 3-4 weeks each, interrupted by periods of decreased dosage.—Schweizerische medizinische Wochenschrift, March 4, 1933.

The Effect of Cement Dust upon Workers.

-Albert E. Russell presents a study the purpose

cancer, but was found in about 30 per cent of cases known to be cancer. At this period they felt justified in recommending the wider use of the method, but they have more recently been having the experience that they obtain no positive results at all in either cancerous or noncancerous patients, notwithstanding they use a Berlin blue solution that is above suspicion, furnished by Lederer himself, and prolong their observations over 4-5 days in the hope of obtaining flocculation. In over 50 per cent of cases among their recent material they have had no clouding, while in the remainder they have had flocculation in only one or at most two tubes, which according to both their own and Lederer's standard had to be considered negative. are therefore compelled to regard the Lederer reaction as unreliable on the basis of their own observations.—Deutsche medizinische Wochenschrift, February 24, 1933.

Treatment of Nonvalvular Heart Disease of Middle and Old Age.—Henry Jackson writing in the New England Journal of Medicine, March 16, 1932, ceviii, 11, emphasizes the importance of the myocardium in diseases of the heart and states that a study of his cardiac cases shows that fully 75 per cent of them were not due directly to valvular disease. Clinically the difficulties of the heart of old age are apparent when the heart muscle has been impaired by overwork, by strain, often without the concurrence of any severe acute process and very often without a strain dependent upon high blood pressure. LEGAL

PROPERTY RIGHTS IN GIFTS GIVEN IN CONTEMPLATION OF MARRIAGE

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York.

An unusual case involving a very human situation recently eame before one of the Appellate Courts of this state for decision. The court was called upon to solve the very interesting question as to the right of a jilted suitor to recover back an engagement ring given by him in anticipation of marriage. The facts briefly were these: According to the allegations of the plaintiff's complaint he had exchanged with the defendant mutual promises to marry and had given her an engagement ring of the value of \$350.00. claimed was given in anticipation of their marriage and conditioned upon the fulfillment by the defendant of her promise to marry him. Subsequently the defendant refused to marry him, although he stood ready to marry her, and she declined to return the ring. Upon a motion, the complaint was dismissed as failing to state facts sufficient to constitute a cause of action. An appeal was taken from that ruling thereby squarely presenting the question of whether a woman, having accepted her suitor, may keep an engagement ring, after she has refused without cause to marry him.

The Appellate Court reversed the ruling of the lower court holding that the complaint stated a good cause of action. The court summarized the rule as follows:

"It has been held that an engagement ring is in the nature of a pledge for the contract of marriage, and that if the recipient break the contract, she should return the ring. Such a ring is a symbol hallowed by social usage. That it is a conditional gift seems inherent in its very purpose. Possession should be retained during the engagement, which it symbolizes, and is changed into firm ownership upon marriage. When the engagement fails the symbol of its existence should be returned to him who gave it.

"Of course, an engagement ring differs from gifts made to secure a lady's favor or gain her affection, which are unconditional.

"The weight of authority seems to go further and hold that any gift to the lady to whom the donor is engaged to be married, made in contemplation of marriage, is conditional, and upon breach of the marriage engagement by the recipient the donor may recover the property."

The court in making its decision referred as authority to an old case which was decided in England nearly two hundred years ago in which an action was brought to recover the value of a and therefore must return the ring."

present that had been given to a lady who afterwards broke her engagement and married another. The Lord Chancellor laid down the law as follows in that case:

"I think, in cases of this nature, these rules may be laid down: That if a person has made his addresses to a lady for some time, upon a view of marriage, and upon reasonable expectation of success, makes presents to a considerable value, and she thinks proper to deceive him afterwards, it is very right that the presents themselves should be returned, or the value of them allowed to him; but, where presents are made only to introduce a person to a woman's acquaintance, and by means thereof to gain her favor, I look upon such person only in the light of an adventurer, especially where there is a disproportion between the lady's fortune and his, and therefore, like all other adventurers, if he will run risques, and loses by the attempt, he must take it for his pains."

In 1917 the question again rose in England in the Court of Kings Bench and the Court repeated the rule of the old case, and in support of the ruling made a study of the history of the engagement ring which is worthy of note and consideration. The court in the opinion said:

"The history of the engagement ring is interesting. We read in the Book of Genesis that Abraham presented earrings when Rebecca was betrothed to Isaac. And no doubt the story represents the ring in those days as a sign or symbol of an agreement to carry out a bargain and sale of the woman. When one comes to the time of civilized law the woman ceases to be a chattel, and one finds in Justinian the ring used as an 'arrhabo,' or a pledge for the contract of marriage or sponsalia. This found its way even into early English law. Times, however, are changed now; but though the origin of the engagement ring has been forgotten it still retains its character of a pledge or something to bind the bargain or contract to marry, and it is given on the understanding that a party who breaks the contract Whether the ring is a pledge must return it. or a conditional gift, the result is the same. The engagement ring given by the plaintiff to the defendant was given upon the implied condition that it should be returned if the defendant broke off the engagement. She did break the contract

The distinction drawn between gifts given a lady to gain her favor and gifts conditioned on the contemplated marriage is well illustrated in a case decided some time ago in one of the New England States. In that case the facts were that the plaintiff and the defendant had become engaged in Minneapolis and it was agreed that she was to come to Vermont to be married. He sent to her sums amounting to \$275.00 for the purpose of buying her wardrobe in preparation for the marriage, and \$55.00 for travelling expenses to come to Vermont. She bought the clothes but instead of coming East she broke the engagement and married another man. The plaintiff sued to get back the sums he had sent her. In ruling that the plaintiff was entitled to recover the money the court said:

"The \$275 stands differently from the \$55 in this respect that it was literally applied to the purpose for which it was given; yet it stands precisely like the \$55 in that it was to be applied by

the defendant towards the consummation of the marriage engagement. She received both sums for a specific purpose, and when she broke the engagement the law raised a promise on her part to refund them. The plaintiff did not given them to her 'as an adventurer,' to help him win her favor, but in consideration of the engagement and to enable him to perform it. When she broke it he was entitled to have his money refunded. We hold that the gifts were not absolute, but conditional and that when the condition failed a right of action accrued to the plaintiff to recover the money."

The propriety of the decisions seems clear. Good taste and fairness would seem to require the return of gifts that have been given by an accepted suitor who is later rejected through no fault of his own, when the gifts are given with the understanding whether expressed or not that they are given solely in contemplation of an impending marriage.

GAUZE SPONGE SWALLOWED BY CHILD

A specialist in nose and throat cases was called by a general practitioner to the hospital with which he was associated for the purpose of examination and operation upon a child six years of age, whom he found to be suffering from hypertrophied tonsils and adenoids. He suggested an immediate operation and the parents of the child consented to same. The patient was put under a general anesthetic and the tonsils and adenoids removed by the snare and dissecting method. There was no unusual hemorrhage at the operation, but in order to guard against possible hemorrhage the doctor placed a gauze plug or sponge into the tonsil fossa. To the said gauze was attached a string which the doctor ran out of the patient's mouth and looped over the patient's ear. In addition the doctor pasted a piece of adhesive plaster over the string fastening it tightly to the patient's cheek. He instructed the interne who had assisted him at the operation to remove the sponge in about an hour. Several hours later when the doctor was again at the hospital he went to the children's ward and examined the boy and found at that time that the adhesive plaster and the sponge were both gone. The doctor assumed that the interne had removed the gauze in accordance with instructions given him. boy's condition was in every way satisfactory. The next day the boy left the hospital. Two days subsequent thereto the doctor was called to the boy's home where he was told that the child had

vomited a piece of gauze. The parents exhibited the gauze and the doctor found that it resembled the piece of gauze which he had inserted in the boy's throat at the time of the operation. The string and adhesive tape were still attached to it. The doctor examined the child carefully and found that he was progressing normally in every way. The doctor saw the child again at his office a few days later and again his condition was excellent.

Suit was brought against the doctor to recover damages, charging him with negligence in the performance of the operation in that he permitted a foreign substance to remain lodged in plaintiff's throat and that due to his carelessness the same was not removed properly by the doctor and was swallowed by the child, causing him damages. It was alleged that the result to the child was that he suffered nausea, dizziness, loss of appetite and became weak and feeble.

The case came to trial and at the close of testimony introduced on behalf of the plaintiff a motion was made to dismiss the complaint on the ground that the plaintiff failed to make out a cause of action against the doctor. The court indicated that the motion would be granted and thereupon the attorney for the plaintiff moved for leave to discontinue the matter against the doctor. Said motion was granted, and the case was discontinued, thereby finally terminating the action in favor of the doctor.

NEWS NOTES

THE ANNUAL MEETING

The 127th annual meeting of the Medical So ciety of the State of New York, which was held April 3-5, 1933, in the Waldorf-Astoria Hotel, New York, was the most extensive and satisfactory in the lustory of the Society. This success is what one would naturally expect in view of the great progress that the medical profession of the State of New York has made in all lines of medical activity, many of which were in their formative stage only a decade ago.

Many factors contributed to the broad scope and high standard of the meeting, not the least being the Waldorf-Astoria Hotel, which provided abundant space and accommodations for every meeting and activity. Every feature of the meeting was easily approached and readily accommodated. The cooperation of the hotel management was all that could be desired, and only praise of it was expressed by the members.

The success of the annual meeting was the result of the judgment of those who planned it. The several officers and committeemen were men of imagination as well as experience, who were able to enact every feature of the program in their minds, so that the meetings and exhibits unfolded themselves like a well rehearsed play or pageant in a theatre.

The program of the annual meeting had been in the process of development for months and the completed plans were presented in the Journal of March first, with mere minor changes annunced in the Journals of March fitteenth and April first. The members of the State Society were fully informed of the good things they could see and hear, and their response was extremely gratifying, for 1,650 physicians recorded their presence, a registration that was by far a record-breaker.

HOUSE OF DELEGATES

The meeting of the House of Delegates on April 3 and 4 was conducted with harmony, and the business was transacted with speed and good judgment. The arguments on the propositions were made with good feeling, and the sersions were fruitful in confirming the plans and propositions submitted by the officers and committees in their annual reports.

The outstanding action was the report of the special committee appointed to consider the report of the National Committee on the Costs of Medical Care, which was briefly described in this Journal of December 15, 1932, page 1432. The members of the House of Delegates gave their undivided attention to the reading of the report by Dr Arthur W Booth, Chairman of the special committee, and voted unanimously for its adoption. This report is printed on page 499, and is the subject of an editorial comment on page 529 of this Journal

The mangural address of the mooning President of the State Society, Dr Frederick H Flaherty, of Syracuse, was given on Tuesdry morning, in accordance with Section 8 of Chapter 2 of the by-laws of the Society This address is published on page 497 of this Journal

A new feature of the Delegates' Dinner which was held between the afternoon and evening sessions on Monday, was four after dinner addresses on subjects of medical administration

Dr Emil Koffler, of New York City, described the workings of the compulsory health insurance systems in England and Continental Europe Dr Koffler outlined the same views which he had given in his leading article in this Journal of April 15, 1932, page 437

Dr Henry F Vaughan, Commissioner of Health of Detroit Michigan, described the methods by which the Department of Health of his city had developed a system of making every family doctor an agent of the Department in the distribution of preventive services, thereby abolishing Department Clinics, and making the office of each doctor a chine. The physicians were pud for their services and the cost to the city is less than the item which had formerly been paid for the hospital care of patients who became sick in the days before preventive medicine had become generally practiced

An outline of a similar address by Dr Vaughan before the Second District Branch was published in this Journal of December 1, 1932, page 1383

Dr Stuart Pritchard, of Battle Creek, Michigan, gave a brief outline of the preventive work done in rural schools of Michigan, under the auspices of the Kellogg Foundation
This work was largely preventive and educative

Dr G F McCleary, Medical Officer of the Ministry of Health of England, described the advantages of the panel system of medical care inder the State Insurance plan of giving medical treatments

The distinction drawn between gifts given a lady to gain her favor and gifts conditioned on the contemplated marriage is well illustrated in a case decided some time ago in one of the New England States. In that case the facts were that the plaintiff and the defendant had become engaged in Minneapolis and it was agreed that she was to come to Vermont to be married. He sent to her sums amounting to \$275.00 for the purpose of buying her wardrobe in preparation for the marriage, and \$55.00 for travelling expenses to come to Vermont. She bought the clothes but instead of coming East she broke the engagement and married another man. The plaintiff sued to get back the sums he had sent her. In ruling that the plaintiff was entitled to recover the money the court said:

"The \$275 stands differently from the \$55 in this respect that it was literally applied to the purpose for which it was given; yet it stands precisely like the \$55 in that it was to be applied by

the defendant fowards the consummation of the marriage engagement. She received both sums for a specific purpose, and when she broke the engagement the law raised a promise on her part to refund them. The plaintiff did not given them to her 'as an adventurer,' to help him win her favor, but in consideration of the engagement and to enable him to perform it. When she broke it he was entitled to have his money refunded. We hold that the gifts were not absolute, but conditional and that when the condition failed a right of action accrued to the plaintiff to recover the money."

The propriety of the decisions seems clear. Good taste and fairness would seem to require the return of gifts that have been given by an accepted suitor who is later rejected through no fault of his own, when the gifts are given with the understanding whether expressed or not that they are given solely in contemplation of an impending marriage.

GAUZE SPONGE SWALLOWED BY CHILD

A specialist in nose and throat cases was called by a general practitioner to the hospital with which he was associated for the purpose of examination and operation upon a child six years of age, whom he found to be suffering from hypertrophied tonsils and adenoids. He suggested an immediate operation and the parents of the child consented to same. The patient was put under a general anesthetic and the tonsils and adenoids removed by the snare and dissecting method. There was no unusual hemorrhage at the operation, but in order to guard against possible hemorrhage the doctor placed a gauze plug or sponge into the tonsil fossa. To the said gauze was attached a string which the doctor ran out of the patient's mouth and looped over the patient's ear. In addition the doctor pasted a piece of adhesive plaster over the string fastening it tightly to the patient's cheek. He instructed the interne who had assisted him at the operation to remove the sponge in about an hour. Several hours later when the doctor was again at the hospital he went to the children's ward and examined the boy and found at that time that the adhesive plaster and the sponge were both gone. The doctor assumed that the interne had removed the gauze in accordance with instructions given him. The boy's condition was in every way satisfactory. The next day the boy left the hospital. Two days subsequent thereto the doctor was called to the boy's home where he was told that the child had

vomited a piece of gauze. The parents exhibited the gauze and the doctor found that it resembled the piece of gauze which he had inserted in the boy's throat at the time of the operation. The string and adhesive tape were still attached to it. The doctor examined the child carefully and found that he was progressing normally in every way. The doctor saw the child again at his office a few days later and again his condition was excellent.

Suit was brought against the doctor to recover damages, charging him with negligence in the performance of the operation in that he permitted a foreign substance to remain lodged in plaintiff's throat and that due to his carelessness the same was not removed properly by the doctor and was swallowed by the child, causing him damages. It was alleged that the result to the child was that he suffered nausea, dizziness, loss of appetite and became weak and feeble.

The case came to trial and at the close of testimony introduced on behalf of the plaintiff a motion was made to dismiss the complaint on the ground that the plaintiff failed to make out a cause of action against the doctor. The court indicated that the motion would be granted and thereupon the attorney for the plaintiff moved for leave to discontinue the matter against the doctor. Said motion was granted, and the case was discontinued, thereby finally terminating the action in favor of the doctor.

THE TECHNICAL EXHIBITS

The Technical or Commercial exhibits were of greater extent and interest than ever before, and the physicians took a special interest in them. Over sixty booths were occupied by the exhibi-The aisles were wide and visitors could move about without crowding.

Following the eustom of recent years the Society tendered a supper and entertainment to the exhibitors and the assistants on Monday evening. Mr. Joseph B. Tufts, the advertising manager of the Society, presided, and Dr. S. I. Kopetzky, Chairman of the Committee on Arrangements, welcomed the guests in a gracious speech.

The attention and courtesies showed to the exhibitors by the Society and the interest taken by

Dr. Thomas Parran, Jr., State Commissioner of Health, Albany, on The Health of the State. Dr. Olin West, Secretary of the American

Medical Association, Chicago, Illinois, on The Community and the Physician.

A special value of the Open Meeting was that it demonstrated the methods which outstanding leaders follow in informing the public about the prevention of the diseases which they discussed. These addresses were widely copied in the daily newspapers, especially those of the Metropolitan area, and all received favorable comment from both physicians and laymen.

the visiting doctors were highly valued by the exhibitors, whose friendly attitude is indicated by the following unsolicited letter of appreciation sent to Mr. Tufts:

"I just want to inform you that we are very well satisfied with the response of the physicians in attending our booth at the 127th annual meeting of the New York State Medical Society.

"The writer would say, that this has been one of the finest conventions he has had the pleasure

of attending."

Since the exhibitors are patrons of the advertising pages of the Journal, they are the co-operative friends of all members of the State Society.

PRESS PUBLICITY

A highly successful innovation in the plans for the annual meeting was provision for Press Publicity. The proceedings of the Medical Society of the State of New York are of civic interest, and are increasingly so in these modern days when official boards of municipalities. States, and the nation are asked to appropriate funds for public health work and giving medical service to the poor.

Physicians consider the newspapers to be among the most important means of transmitting medical news to the people; and this year, for the first time, the Medical Society of the State of New York made provision for giving out the news of the annual meeting to the recorters, and supplying them with advice regarding the form of their articles.

The Society provided a large room which was easily accessible to the reporters, and furnished it with typewriters and a mimcograph and clerical help. The service was in charge of Mr. Dwight Anderson, Director of Publicity of the National Tuberculosis Association of the addresses were prepared either " the staff or by the authors themselves, and mimeographed copies were made and given to the reporters.

The newspapers were cordial in their utilization of the press service, and gave a generous amount of space to the Medical Society news, averaging two columns in each issue of the great Metropolitan dailies. The newspapers gave especial prominence to the radio addresses given under the auspices of the Society. Mimeographed copies of these addresses were available to all reporters who desired them.

Supplying modern medical service is no longer confined to an individual doctor dealing with an individual sick person. The service of medicine is also a civic activity in which the people collectively have a part, and in which physicians as an organization must assume the leadership. The extent of the participation of organized physicians in the practice of civic medicine is indicated by the scope of the program of the annual meeting of the Medical Society of the State of New York. The newspapers are essential agents for spreading a knowledge of medical activities and responsibilities among the people.

The election on Tuesday morning resulted in the choice of the following officers:

the choice of the following officers: President-elect, Arthur J. Bedell, Albany.

Vice-Presidents, Ralph R. Fitch, Rochester, Charles D. Kline, Nyack.

Speaker of the House of Delegates, Samuel J. Kopetzky, New York.

Vice-Speaker of the House of Delegates, Floyd S. Winslow, Rochester.

Trustee for Five Years, George W. Cottis, Jamestown.

Chairman of Committee on Economics, Frederick H. Elliott, Brooklyn.

The other officers were reelected. A full list of the officers appears on page 528.

It is expected that the minutes of the House of Delegates will be printed in full in the Journal of May first.

SCIENTIFIC SECTIONS AND SESSIONS

Following the precedent of last year, scientific papers of common interest to all the members of the Society were presented in two general sessions, held on the afternoons of Tuesday and Wednesday.

The mornings of those two days were devoted to the specialties which were organized in eight sections. A special session on radiology was conducted on Tuesday morning, and one on physical therapy on Wednesday morning.

The attendance at the scientific sections was unexpectedly large, and the meeting rooms were filled to overflowing.

The scientific papers were of unusual practical value and interest, and will be published in this Journal during the year.

SCIENTIFIC EXHIBITS

An extensive series of scientific exhibits was collected under the leadership of Dr. F. E. Sondern. This collection included pathological specimens, x-ray films, photographs, charts, models, and scientific apparatus. Fifty separate collections were listed in the program of the meeting, and altogether about two thousand specimens were shown. A valuable feature was the presence of lecturers and demonstrators, who explained the special features of the exhibits and their relation to the practice of scientific medicine.

The racks and tables used for the display of the exhibits were loaned by the New York Academy of Medicine from the extensive collection which it maintains for the use of its own exhibits. The exhibits were put up, supervised and removed under the direction of Mr. Harold Maddocks, Superintendent of the building of the Academy, and a staff of assistants experienced in the work.

The exhibit was popular with the physicians, and will doubtless be made a feature of every annual meeting.

THE FORMAL ANNUAL MEETING

The session which is formally called the annual meeting was conducted as the after-dinner part of the Annual Banquet, which was held on Tuesday evening in the Grand Ball Room. About one thousand physicians and their wives were present. The program was as follows:

Presidential address, "The Medical Society of the State of New York; Our Responsibilities and Our Obligations," by Dr. Chas. Gordon Heyd, New York. This address is printed as the leading article in this Journal.

Address: "Medical Science for the Nation,"

by Dr. Edward H. Cary, Dallas, Texas, President of the American Medical Association.

Address: "The Decline of Medicine as an Art," by Dr. Howard W. Haggard, Yale University, New Haven, Connecticut.

Address: "The Master in the House of Medical Paragraphy of Med

Address: "The Master in the House of Medicine," by Dr. Alphonse M. Schwitalla, Dean of the School of Medicine, St. Louis University, St. Louis, Missouri.

The addresses of Drs. Cary, Haggard, and Schwitalla will be published in an early issue of this Journal.

THE OPEN MEETING

A new feature of the Annual Meeting was what was called an "Open" meeting, because it was designed to inform laymen regarding medical subjects which they should understand. This meeting was held on Wednesday evening in the Grand Ballroom of the Waldorf-Astoria. Ad-

mission was free, but by ticket, and the room was filled to overflowing. Blocks of seats had been requested for students in educational institutions such as Columbia University, the Pratt Institute, and the Schools for Nursing. Addresses were given on what the community should know

about common conditions, the speakers being well known physicians, as follows:

Dr. Lewellys F. Barker, Baltimore, on Arth-

Dr. Frank H. Lahey, Boston, on Goiter.

Dr. Dean DeWitt Lewis, Baltimore, on Appendicitis.

Dr. Elliott P. Joslin, Boston, on Diabetes. Dr. William D. Stroud, Philadelphia, on Heart

Dr. Burton J. Lee, New York City, on Caneer, Dr. Wendell C. Phillips, New York City, on the Hard of Hearing.

Dr. Thomas Parran, Jr., State Commissioner of Health, Albany, on The Health of the State. Dr. Olin West, Secretary of the American Medical Association, Chicago, Illinois, on The

Community and the Physician.

A special value of the Open Meeting was that it demonstrated the methods which outstanding leaders follow in informing the public about the prevention of the diseases which they discussed. These addresses were widely copied in the daily newspapers, especially those of the Metropolitan area, and all received favorable comment from both physicians and laymen.

THE TECHNICAL EXHIBITS

The Technical or Commercial exhibits were of greater extent and interest than ever before, and the physicians took a special interest in them. Over sixty booths were occupied by the exhibitors. The aisles were wide and visitors could move about without crowding.

Following the custom of recent years the Society tendered a supper and entertainment to the exhibitors and the assistants on Monday evening. Mr. Joseph B. Tufts, the advertising manager of the Society, presided, and Dr. S. J. Kopetzky, Chairman of the Committee on Arrangements, welcomed the guests in a gracious speech.

The attention and courtesies showed to the exhibitors by the Society and the interest taken by

the visiting doctors were highly valued by the exhibitors, whose friendly attitude is indicated by the following unsolicited letter of appreciation sent to Mr. Tufts:

"I just want to inform you that we are very well satisfied with the response of the physicians in attending our booth at the 127th annual meeting of the New York State Medical Society.

"The writer would say, that this has been one of the finest conventions he has had the pleasure

of attending."

Since the exhibitors are patrons of the advertising pages of the Journal, they are the cooperative friends of all members of the State Society.

PRESS PUBLICITY

A highly successful innovation in the plans for the annual meeting was provision for Press Publicity. The proceedings of the Medical Society of the State of New York are of civic interest, and are increasingly so in these modern days when official boards of municipalities. States, and the nation are asked to appropriate funds for public health work and giving medical service to the poor.

Physicians consider the newspapers to be among the most important means of transmitting medical news to the people; and this year, for the first time, the Medical Society of the State of New York made provision for giving out the news of the annual meeting to the reporters, and supplying them with advice regarding the form of their articles.

The Society provided a large room which was easily accessible to the reporters, and furnished it with typewriters and a mimeograph and clerical help. The service was in charge of Mr. Dwight Anderson, Director of Publicity of the National Tuberculosis Association histracts of the addresses were prepared either the staff

or by the authors themselves, and mimeographed copies were made and given to the reporters.

The newspapers were cordial in their utilization of the press service, and gave a generous amount of space to the Medical Society news, averaging two columns in each issue of the great Metropolitan dailies. The newspapers gave especial prominence to the radio addresses given under the auspices of the Society. Mimeographed copies of these addresses were available to all reporters who desired them.

Supplying modern medical service is no longer confined to an individual doctor dealing with an individual sick person. The service of medicine is also a civic activity in which the people collectively have a part, and in which physicians as an organization must assume the leadership. The extent of the participation of organized physicians in the practice of civic medicine is indicated by the scope of the program of the annual meeting of the Medical Society of the State of New York. The newspapers are essential agents for spreading a knowledge of medical activities and responsibilities among the people.

RADIO PROGRAM

A new feature of the annual meeting was the system of radio broadcasts which had been arranged by Dr. Iago Galdston, Director of the Medical Information Bureau under the joint auspices of the Medical Society of the County of New York and the New York Academy of Medicine. The program was carried out according to the program which was printed in the Journal of April first, page 466. Thirteen addresses were given by as many speakers from eight stations. The speakers were outstanding men in their subjects, as is shown by the first three men listed on the program, as follows:

Dr. C. F. McCleary, Medical Officer of the Ministry of Health, England, on "Recent Advances in Child Welfare."

Dr. Burton J. Lee, Cornell University, on "Cancer and the Community."

Dr. Chas. Gordon Heyd, President of the Medical Society of the State of New York, on "The Doctor—Fact and Fiction."

The talks had a two-fold value:

1. They were models of what practical physicians consider to be the best adapted for educating the people in medical and public health subjects.

2. They informed the people regarding the Medical Society of the State of New York and of the desire of the medical profession to instruct

the people regarding their health.

Evidences of the appreciation of the radio talks are the comments which listeners have made to the physicians after their return from the annual meeting, many saying "That must have been a great meeting which you attended. I heard the radio talk given by the State Medical Society."

PRIZE ESSAYS

Two prizes for the best essays on subjects of medical research submitted in a contest under the auspices of the Medical Society of the State of New York were awarded at the annual meeting by a Committee consisting of Dr. H. M. Lyle, Chairman; Dr. Martin Cohen, and Dr. Joshua E. Sweet.

The Merritt H. Cash prize was awarded to Dr. H. Hamilton Cooke, of the Lewis County General Hospital, Lowville, N. Y., for his essay entitled "A Pathological, Experimental, and Clinical Study of Lipoid Deposits in the Gall Bladder." This essay formed a bound volume of 250 typewritten pages, with photographs and tables. The volume took up the general study of the gall bladder, its embryology, anatomy and pathology; and then discussed the lipoids, especially cholesterol, and their relation to the chemistry and pathology

of the gall bladder, and the basic principles of the treatment of the conditions found in the gall bladder.

The second part of the essay consisted of a detailed study of five hundred cases found in human beings, and a report on experiments on animals.

The Lucien Howe prize was awarded to Dr. Julius Ferber, of New York, for his essay on "The present status of thromboangiitis obliterans, with special reference to its treatment by intravenous injections." Dr. Ferber first discussed the disease from the standpoint of pathology, diagnosis, and treatment; and then took up its treatment of the disease by the injections of considerable quantities of saline solutions. The research part of his paper consisted of a detailed record of the blood pressure before and after the injections.

DEMONSTRATION OF WORKMEN'S COMPENSATION ARBITRATION

The demonstration of arbitration of doctors' fees in Workmen's Compensation cases in connection with the Annual Meeting was conducted by Dr. Morris Rosenthal, Director of the Bureau of Compensation Arbitration of the Medical Society of the County of New York, as announced in this Journal of April first, page 467. This demonstration was attended by fifty visiting physicians, and was eminently satisfactory to them. The arbitration on ten compensation cases

were heard and each was judged by a jury of visiting physicians assigned with the consent of both the insurance company and the doctor who treated the case. The visitors were impressed with the rapid disposal of the cases by commonsense methods, and the fairness of the decisions. They felt that the method of arbitration followed by the New York County Medical Society might well be adopted by the other county societies of the State.

COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations of the Medical Society of New York State met at the Queensbury Hotel in Glens Falls on March 17, 1933. All members of the Committee were present, also representatives of the counties of Essex, Rensselaer, Saratoga, Montgomery, Schenectady, Albany, and Warren.

Dr. Hoffman spoke for Warren County. He said that the Board of Supervisors has a Public Health Committee with a physician chairman. They are undertaking venereal disease control without holding clinics by having the county health nurse take the indigent venereal disease case to the nearest doctor able to treat the case, whose bill will be audited and paid by the county.

Maternity clinics and eye work are under the county Public Health Committee and are administered in the same way as the venereal disease control. No orthopedic clinics are now held.

Warren County has good working relations with the lay health organizations. "There are too many of them but all is going well enough," The doctors get no compensation from the Welfare Commissioner,

Dr. Hoffman said that they had established an Academy of Medicine for the purpose of advancing medical publicity and medical education by having prominent speakers from time to time. Some of them will be furnished by the Albany Medical College.

Dr. Mazlan, Chairman of the Public Health Committee of the Warren County Medical Society, said that they were trying to keep the practice of medicine in the County Medical Society, and still be fair to the taxpayers of the county. He said that they had no trouble with the Board of Supervisors in health matters.

Warren County has forty thousand population and spends sixty thousand dollars for public health in all of its features. The Supervisors' Public Health Committee is made up of three laymen, two Supervisors, and two doctors. Clinics are carried on by local men. Laboratory services are available for indigent cases when referred by the doctor. The County Medical Society is the leader in all health work.

Dr. Fraser, President of the Warren County Medical Society, said that its Committee on Public Relations had brought about a desirable relationship between the medical profession and lay organizations and that the Committee had done a great deal in establishing the Academy of Medicine which was essentially an educational project.

Dr. Cummins of Essex County said that they had one public health nurse and no Committee on Public Relations. They have had much unemployment. They had, however, taken care of the sickness of the unemployed. Dr. Cummins may have referred to the mining community in

which he is working on salary. There are clinics held by the State Health Department and people may go there without being sent by a doctor. They have no machinery for emergency work in Essex County. There are Red Cross town associations.

Dr. Hemstreet of Rensselaer County said that there are many people going to the clinics of each hospital now and that he was afraid that these people would always want to go. He said that the profession had made a plan to control the attendance and keep the service for the indigent. They have three eards—a plan proposed by the County Medicat Society. Hospitals will cooperate. The idea is to get those not deserving of free care away from clinics.

Dr. Conant of Montgomery County (seventy thousand population) read Dr. Charles Stover's report. Medical welfare is taken care of in the City of Amsterdam by two eity physicians, but they are trying to get these two men to resign and have the work done by the family physicians. Physicians are not paid for their work for the indigent. Cooperation of the medical profession and the lay organizations is good. There is no friction anywhere.

Dr. Goodfellow of Saratoga Springs said that the indigent are cared for at the Saratoga Hospital. Clinics are run by the hospital. Maternity elinics are run by the State. Tuberculosis clinics are run by the Tuberculosis Sanatorium. They have cordial relations with the Health Committee. There is a county laboratory. There are four County Medical Society meetings a year. Staff meetings are held once a month. Hydrotherapy is advancing in this section.

Dr. Treder of Schenectady County said that the Board of Supervisors had asked the profession to help it in the administration of medical welfare. He said that there was much objectionable administration of clinics; that the profession was endeavoring to have the indigent go to doctors' offices; that the County Society objected to the fees established by the Public Welfare Department of the State. The city has three physicians at \$800 a year, whose work amounts to 27 cents a call. He said that they saw no solution of their problems in Schenectady County except to have a county health unit. Dr. Treder favored a county health unit and the County Society favored it.

No one was present to report for the counties of Fulton, Washington, Franklin, and Clinton.

Dr. Lawrence presented for the Committee on Public Relations of Albany County a survey of about one hundred fifty pages which was a study of the relations of physicians, dentists, and nurses; and of the health activities of all groups, including various societies, churches and insurance agencies. The report consisted of correspondence and replies, telling what they were doing and how. It contained a study of forty-nine social agencies and forty-nine health programs, and the amount of money income of each. The report

said that there was an expenditure of \$2,468,764,

for many activities touching upon health and welfare, such as crippled children, community chests, and feeding and clothing the hungry. No conclusions were reached.

W. H. Ross, Secretary.

LEGISLATION

The Legislature of New York State adjourned on Monday, April 10, 1933, at 4:30 P. M., after defeating the bills on osteopathy, chiropractic,

antivivisection, and physical therapy.

The last week of a session of the Legislature is always crowded with rapid changes of events. The Legislative Bureau of the Medical Society of the State of New York sent out the regular bulletins, numbers 11 and 12, and three special bulletins, and kept the Chairmen of the County committees fully informed of the course of the bills. A supplementary bulletin will be issued and printed in the Journal of May first, outlining the history of the principal bills in which physicians are interested.

Temporary Emergency Relief Administration: Legislative bulletin number 12 carried the following advice to physicians in regard to the medical relief of the indigent:

Dr. James Vander Veer's special committee which has been working with representatives of the Temporary Emergency Relief Administration in an effort to perfect a way by which that organization can assist county and town commissioners of public welfare in providing medical care for the indigent, has received a number of letters from physicians in the state asking for further information regarding certain phases of the matter. These are:

First, the manner of securing authorization. One physician wrote that his commissioner has no telephone and lives quite a distance from him and that if he were obliged to secure authorization for every case, it would mean that his mileage to and from the commissioner might be greater than that expended in reaching the patient. The committee recommends that authorization for treatment should be secured by the patient. He is obliged to secure authorization for the purchase of food and clothing and present such authorization to the merchant, and there is no reason why the same procedure should not be followed when he desires medical service. Of course, the first call by the physician can be made without authori-

zation, but at that time the patient should be informed that before further service is rendered, signed authorization should be secured from the welfare officer.

Second, whether mileage should be charged and who should pay it, is the subject for discussion in certain districts. Dr. Vander Veer's committee and the T.E.R.A. made no mention of mileage, because conditions vary so greatly in the different counties that they thought it impossible to make any general statement that would apply more or less fairly to all sections of the state. The best solution of this problem, it seems, would be that the custom which now prevails among the physi cians with regard to mileage should maintain when the case is one authorized by the commis sioner. If the local physicians feel that in cases of this character they might make a reduction of certain amount from the regular mileage fee, tha is a matter for local arrangement between the physicians and the welfare officer. The T.E.R.A has said, however, that if there are many instance where there is much mileage connected with th welfare work, it would make an effort to devis a plan by which it could compensate the welfar officer in a measure for such expenditures. It order to have some knowledge of this, it is sug gested that physicians who are obliged to trave great distances in their welfare work, send to Di Vander Veer statements of their mileage for pe riods of a week, two weeks or a month, and i any number of such statements are receive demonstrating that many long trips are necessary a basis may be reached by which the T.E.R.A can offer to refund to the welfare officer a cer tain portion of such expenses.

Third, in rural districts where the physicia does not write prescriptions, but dispenses his ow drugs, he should be compensated for those drugs their cost should not be included in the house vis fee, and the welfare officer will receive a refun from the T.E.R.A. for such cost in the same mar ner as he would if he were paying the bill to the

druggist.

THE DAILY PRESS

SPEED LIMITS

The possible speed attainable by an automobile is limited by the human capacity of the driver, as is shown in the following editorial in the New York Times of February 24:

"It was almost a superhuman performance that Sir Malcolm Campbell gave when he made his world's record of 272.108 miles an hour. Fame or death was the reward of two runs of about thirteen seconds each. In the white mist that hung over the sands he could see but two seconds ahead. Brakes were almost comical accessories at this fearful pace, useless at speeds of over 100 miles an hour.

"It takes about four-tenths of a second for the trained brain of so skilled a driver as Sir Mal-

colm to tell his muscles what to do. In that time the Blue Bird can cover 398 feet. Marking flags 100 yards apart flicker past like pickets in a fence. Instinct rather than sight guides the hand. Campbell expresses disappointment at not having attained 285 miles an hour because of the poor condition of the beach. Others have hinted at 400. The Blue Bird's steady improvement since 1924, after four rebuildings, shows that the engineering limit to speed is not yet in sight. But what of the human limit? One cannot help wondering whether Sir Malcolm has not almost reached it, and whether a car faster and more powerful than the Blue Bird can be controlled at its maximum speed."

FRANKLIN'S INSCRIPTION FOR THE PENNSYLVANIA HOSPITAL

The New York Times of February 28 has the following comment on Franklin's inscription for the cornerstone of the Pennsylvania Hospital:

"Benjamin Franklin is so much the sage and statesman that people are apt to forget what a first-rate literary draftsman he was. No man, said Dr. Johnson, is on his oath in a lapidary inscription, and certainly few men are at their ease in composing any kind of inscription. But the legend which Franklin composed for the cornerstone of the Pennsylvania Hospital—the original manuscript turned up recently in Germany—shows how feeling, grace and decorum may dwell together in one who is a master of style.

"It is as follows:

In the Year of Christ 1755

George the Second happily reigning
(For he sought the Happiness of his People)
Philadelphia flourishing
(For its Inhabitants were publick-spirited)

(For its Inhabitants were publick-spirited)

This Building,

By the Boyerty of the Covernment

By the Bounty of the Government And of many private Persons, Was piously founded,

For the Relief of the Sick and Miserable.

May the God of Mercies

Bless the Undertaking!"

COINING NEW WORDS

Medical authors are prone to use words strange and new that have not yet achieved a place in dictionaries. The question sometimes arises as to when new words become a part of the English language. This problem was discussed editorially in the New York Times of March 25, commenting on a law suit growing out of a contest in coining words out of a given set of letters. The Times said:

"Plaintiffs submitted longer word lists than the winning one's, but were ruled out by the contest judges because many of their words were not 'correct,' in the sense of being moderately familiar. They were highly abstruse technical terms. How would the reader like to meet one dark night on a lonely road a desma, which is 'a stout, irregular spicule, formed by precipitation of silica on a spicular nucleus'?

"All over this wide land the dictionary hounds, stimulated by large money offers from the business world, are running down strange quarry like the desma. And yet where shall the line be drawn? Even when we have eliminated the scientific terms and have brought down the contents of the English language to one-fifth the amount contained in the big dictionaries, say 50,000 words, we shall still have left things like acatalectic pentameter, which on a dark night on a lonely road would be almost as bad as a desma."

The editors of the New York State Journal or Medicine hope that the plaintiffs lose their

suit

COLD WINTERS

The New York *Times* of March 28 discusses cold winters as follows:

"There are two topics of universal and inexhaustible interest to the human race: Why are Winters and Summers not what they used to be? Why are the prices charged by the grocer and the butcher not what they used to be? A composite picture of the past, as memory fondly enshrines it in the average man, would show a little boy going out into 30-below-zero weather to fetch his mother some butter from the store at 5 cents a pound or thereabouts.

"Take note of the announcement by the Weather Bureau at Washington that we are now passing through the warmest Winter cycle since 1776. The Winter of 1931-32 was the warmest Winter in one hundred years in the territory east of the

Rocky Mountains.

"Plainly an apology is due the average citizen from the meteorological pundits. Whenever Jones suggests that our Winters do not seem to be so cold as they used to be he is promptly put in his place by the weather scientists. They tell him it is just like an ignorant layman to argue from personal impressions and one or two accidents or coincidents. Ignorant laymen never give close attention to the long-time record of nature's behavior.

"Well, it turns out that the average man is right about the weather, though the expert, too, is right. It depends on how long a record we consult. If we go back to 1776, the Winters are no warmer than they were then. But in between there have been colder Winters. A warm-Winter curve appears about every fifty to seventy-five years, but that is much further back than most of us can remember. For the average man it is mathematically determined that he shall be living in a period when Winters are either warmer or colder than they used to be."

STATISTICS

Statistics are as puzzling to many of us as they are to James J. Montague, who expresses himself

"I often wish I had the nerve
To plot my future with a curve;
I wish my pathway I could mark
By working out an upward arc,
Or with a graph a spot could find
Where gold and silver might be mined.
If I were just an engineer
I'd face the future minus fear.
A pair of compasses I'd ply
To map the road to by and by,
And over books of tables bend
To ascertain the forward trend,

in a form that is "More Truth Than Poetry" in the New York Herald Tribune of February 20:

By following which my load of care Would shortly be dissolved in air. With instruments I'd calculate The proper time to deviate, What operations to perform In order to reveal my norm, And to envision, as a seer, The things that must occur next year. But figures only puzzle me, And so no future I can see. I'll have to use experience, And, if I've got it, common sense."

JUSTICE HOLMES AS A CHILD

The 92nd birthday of Justice Oliver Wendell Holmes of the United States Supreme Court on March 8, was the occasion for the New York

"The fearless soldier who has faced The serried bayonets' gleam appalling, For nothing save a pin misplaced The peaceful nursery has disgraced With hours of unheroic howling. Sun of that date to quote a poem written by the jurist's father, when the son first became a judge, which says:

The justice who in gown and cap Condemns a wretch to strangulation Has thrashed his nurse and spilled his pap And sprawled across his mother's lap For wholesome law's administration."

ANNUAL MEETING IN PHILIPPINE ISLANDS

The Ianuary number of the *Journal* of the Philippine Islands Medical Association discusses the annual meeting editorially as follows:

"On December 13-16, 1932, Manila, the Philippine City of conventions, once again had the privilege of witnessing an important medical reunion—the annual meeting of the Philippine Islands Medical Association, held at the end of its thir-

tieth year of existence.

"As in the past, and despite the present economic depression, the program of this year's meeting was replete with original and noteworthy contributions in the various branches of medicine, especially clinical medicine and public health. It was gratifying to see that several clinico-experimental studies of some of our medicinal plants and important problems of psychopathological nature were included. It was no less a source of satisfaction to see that the program included also a goodly number of research papers contributed by the medical officers of the United States Army, who cordially cooperated in making the meeting a success. Moreover, Dr. Victor G. Heiser of the Rockefeller Foundation, who was invited to the convention as special guest of the association, contributed illuminating facts regarding worldwide medical problems.

"Above all, however, the members of this convention were particularly fortunate in having had the rare opportunity of listening to the inspiring message of Senate President Manuel L. Quezon and to the significant and encouraging words of

Governor General Theodore Roosevelt.

"Dr. Heiser has emphasized our large death rate and unnecessarily high morbidity. We should not forget that our provincial and rural communities are mostly in need of the blessings of a good water supply and of modern hygienic facilities that will insure protection against intestinal infections. Our tuberculosis rate is entirely too high, and the general undernourishment of our people undoubtedly predisposes them to all sorts of diseases. These are some of the vital

problems that require our collective and united endeavors.

"With our determination to build an independent nation, it is our duty to bring about the improvement of the health and physique of our people. We all know that our sturdy race is the best asset of a nation, and that disease is a decided

liability

"Today, 'education' is the fascinating word that holds the confidence and hopes of all nations. We are among those who have an unflinching faith in it. We blindly believed and still believe that the welfare of humankind, and of our people in particular, lies in the education of the masses; yet, as the years go by and as we observe the slow process and uncertain results of education, we are inclined today to modify our former view, especially on matters concerning public health, in the sense that education alone, without the strict enforcement of the rules and laws governing public health and sanitation, can not eradicate many of the endemic diseases prevalent in our country. The force of habit is strong, and assimilationby which is meant the transforming of a foreign idea or institution into something indigenous truly expressing the native genius of the people -takes time.

"It is not derogatory to our people to state that the majority of the laws and rules of health and sanitation are new in our country. They are also

new in many countries.

"If we will depend, then, only on the slow and uncertain results of education we shall endanger the safety of the present and also that of future generations. Many of the habits and traditions of our people that are not in accord with present scientific knowledge will continue to prevail and will hinder the physical and mental development of our people and country.

"Therefore, if we want to get immediate results we must insert strong teeth into our rules and laws on hygiene and sanitation to make them

more easily and quickly assimilable."

ECONOMICS IN WISCONSIN

The February number of the Wisconsin Medical Journal has the following editorial comment on the economic upheaval which affects doctors as well as other classes of citizens.

"A year ago we had occasion to visit our log cabin in the woods about the first of May. To

and the frame that were as large as two inches in some corners. We called the carpenter post haste that this destruction caused by Mother Nature in the winter months might be remedied even though the bill obviously would be a high one.

"Why man alive! If I were to saw all those

FOR THE NERVOUS PATIENT WHO CAN'T SLEEP

THE ordinary type of nervous insomnia as it affects the neurasthenic, the convalescent or the physically run-down individual, can often be corrected without the use of habit-forming, hypnotic drugs.

When the patient is in need of sound, restful sleep as an aid to rebuilding strength and vitality, physicians frequently recommend a pleasant drink of warm Ovaltine—the Swiss Food-Drink—to be taken just before returing. They find that this tends to allay nervous irritability and so induce sleep in a natural way.

Ovaltine is the Swiss food concentrate

OVALTINE

The Swiss Food - Drinks

Manufactured under license in U.S.A. according to

widely recommended by physicians as a food for invalids and convalescents, for nervous and run-down patients, for growing children, for nursing and expectant mothers and for the aged.

Ovaltine adds important food elements to plain milk and, as it reduces the milk curd to finely communited particles, it enhances considerably its digestibility.

Before recommending Ovaltine, we would like you to make a personal test in your own home. The coupon will bring you a supply with our compliments.

This offer is limited only to practicing physicians, dentists and nurses

DURING PREGNANCY AND THE POSTPARTUM PERIOD

supporting treatment is essential. Fellows' Syrup is the most logically prepared tonic at the disposal of the physician.

It contains all the required minerals in correct proportion and in an easily assimilable form. These are Manganese and Iron to renew the blood stream impoverished by continued loss; Calcium to replenish the constant calcium depletion; Potassium, Sodium, and Phosphorus to overcome the neural depression: Strychnine as a tonic to cell metabolism; and Quinine as a gastric stimulant.

There is no better tonic than Fellows' Syrup to the parturient and post-parturient patient. During these trying periods, the suggested dose is one teaspoonful three times daily well mixed with water.

"We are, therefore, urging all member physicians to read the advertising pages of the Journal and to give their patronage, wherever and when-

ever practicable, to the dealers and manufacturers who have so generously supported our publication. It is only through such patronage of our advertisers by members of the profession that we can hope to continue the Journal in its present size and so be able to take care of all the worthwhile material submitted for publication."

CONFERENCE OF COUNTY OFFICERS IN COLORADO

The February issue of *Colorado Medicine* contains the following account of a conference of County Presidents and Secretaries:

"The meeting was held in the auditorium of the Capitol Life Insurance Company Building, Denver, at 7:30 p. m. Thursday, January 19, with Dr. Frank B. Stephenson, State President, presiding. While attendance might have been greater, nine of the county societies were represented by their presidents, secretaries, or by both president and secretary, four state officers were present, and state committees were generously represented.

"Those attending felt that the meeting would produce more of concrete results in county studies of economic problems, particularly through the 'Iowa Plan' of caring for indigency, than any meeting that has been held in the state. Discussion of the four papers was to the point in each case, and many valuable ideas for improvement of county society activities were exchanged. A buffet supper was served with the compliments of the Walgreen Company at the close of the conference.

"It was voted that an analysis of the 'Iowa Plan' as presented by Dr. Cooper be mimeographed and supplied to all county officers, so that those not present at the conference may study what were considered the most important points brought forth. This will be in the hands of county officers about the time this issue of Colorado Medicine reaches them.

"Following is the program as followed at the conference: (Continued on page 553—adv. xvii)

You Can Recommend This TOMATO JUICE with Confidence

Kemp's SUN-RAYED Tomato Juice has the distinction of being the FIRST tomato Juice accepted by the American Medical Association, Committee on Foods—and the FIRST tomato Juice to submit PROVED VITAMIN POTENCY, verified by scientific feeding tests. This rich, full-bodied, pure tomato Juice is obtainable at nearly all chain food stores and most independent stores in the New York district.

Write for copy of Steenbock report, showing nutritional importance of full-bodied, whole tomato juice over thin juices containing only a portion of the tomato solids

TUBERCULOSIS SANATORIUM IN MINNESOTA

The February number of The Journal-Lancet, of Minnesota contains the following editorial on the changing attitude of the managers of the State Tuberculosis Sanatorium toward family doctors:

"Physicians to the private practice of medicine will hail with delight the announcement in this issue of the program of the Minnesota State Sanatorium. For nearly two decades the private general practitioner conscientiously and honestly diagnosed tuberculosis but the cases were hurried away from him, rarely to be returned. Law organizations and others convinced the public, and even the physician, that he was not capable of treating tuberculosis patients.

"The following statement of Dr. Burns (superintendent of the Sanatorium), is most significant:

"'It is the plan of the Minnesota State Sanatorium to co-operate to the fullest extent with the family doctor, realizing that he is the only successful case-finder and that the responsibility and : " continue to rest with :. " plan outlined, every physician's office becomes a tuberculosis clinic and with this should come the abolition of the so-called free tuberculosis clinic, except for those few operated in our teaching and charitable institutions, where cognizance is given to eligibility; in other words, those operated for the poor. In sparsely populated parts of our state, where physicians' offices are far apart, an occasional tuberculosis clinic of the oldtime type might be justified.

Editor, experienced in literature of medicine and surgery; doctor preferred. Position per-Address GHT, New York State Journal of Medicine.

LITERARY RESEARCH

Current data supplied to physicians from one of the great medical libraries. English and foreign sources. Manuscripts prepared for publication; typing, editing, proofreading, hibliographies. LITERARY RESEARCH BUREAU, 111 East Tenth Street, New York.

COCOMALT

The tendency to give milk to excess in post-operative and convalescent cases is apt to give the patient a feeling of revulsion. Yet milk is the one food for which there can be no effective substitute.

Cocomalt, for example, converts milk into a delicious chocolate flavor fooddrink that is tempting to the fussiest invalid. Even those who acutely dislike milk and refuse to drink it, welcome the refreshing flavor of Cocomalt. Not only does it tempt sick and lagging appetites by its palatability: Cocomalt substantially increases the nutritive value of milk. Every cup or glass of Cocomalt a patient drinks is equal in food-energy value to almost two cups or glasses of milk alone.

Furthermore, Cocomalt nourishes without taxing the digestion. It can be taken frequently even by the very sick. It is easily digested and quickly assimilated even by those whose digestive systems are impaired.

Cocomalt contains a rich supply of Sunshine Vitamin D and is accepted by the American Medical Association Committee on Foods.-Adv.

ZEITSCHRIFT FUR WISSEN-SCHAFTLICHE BADERKUNDE.

Prof. Dr. Hermann Schlesinger

"Gonorrhoe und Lues als Ursache von Gelenkerkrankungen"

(Gonorrhoeal and Syphilitic Diseases of the Joints).

The author writes on the different forms of arthritis having their cause in a gonorrhoeal or syphilitic infection and states that gonorrhoeal affections of the joints as well as late syphilis involvements (arthro-lues tardiva-Schlcsinger) are both easily amenable to treatment. Gonorrhoeal arthritis should be treated early by specific vaccines, diathermy and Bier's hyperaemia (but phlegmonous and suppurative forms should be carefully watched for). In

chronic cases massage and warm baths arc useful. Externally applications of Antiphlogistine show good results. For chronic and obstinate cases baths at different spas are recommended.—Adv.

WHAT IS MALTCAO?

Maltcao is a scientifically prepared health food consisting of pure sugar, malt, cocoa, partially defatted milk, and liberal quantities of organic phos-phates of calcium and iron in the same form as nature produces these salts in grains and vegetables.

"MALTCAO" ANALYSIS:

Moisture	3.03%
Cocoa Butter	4.42%
Butter Fat	.56%
Milk Solids not Fat	10.09%
Crude Fiber	.89%
Canc Sugar	45.07%
Maltose	14.72%
Total Protein	9.87%
Dextrin and Other Carbo-	= 260
hydrates	7.36%
Mineral Ash	3.99%
1	100.00%
The ash contains:	
Sodium Chloride	0.84%
Iron	0.09%
Calcium Oxide	0.52%
Calcium Oxide	0.52% 1.41%
Calcium Oxide	1.41%

IN WHOOPING COUGH

WALIXIR BROMAURATE (Elixir Gold Tribromide)

Reduces the frequency and severity of the coughing spasms and shortens the period of the illness. Also valuable in Bronchial Asthms, Chorea, Migraine and Petit Mal. IN FOUR-OUNCE ORIGINAL BOTTLES. A leaspoonful three or four times a day after meals.

Gold Pharmacal Company, New York Distributed by Schieffelin & Co., New York

THE HOSPITAL COTTAGE

199 Spring Street

Ossining-on-Hudson, N. Y.

Modern facilities for the study and treatment of selected cases. Capacity limited to three patients, assuring individual attention. Admission only by appointment. Telephone Ossining 2340. Physician-in-Charge: Harold Inman Gosline, A.B., M.D., D.N.B.

(PATHOLOGIST APPROVED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION)

THE DECLINE OF MEDICINE AS AN ART

By HOWARD W HAGGARD, MD, NEW HAVEN, CONN

From the Department of Physiology Ante University, New Haven Connecticut Delivered at the Annual Meeting of the Medical Society of the State of New York after the Banquel on the evening of Tuesday April 4 1933 in the Hotel Waldorf Astoria New York City

7HEN you did me the honor to ask me to speak here it was intimated by your Conimittee that I should choose for a topic one that covers some of the reasons why the medical profession of today appears to have lost prestige in the eyes of the public. That is a difficult subject to deal with, especially as I am not convinced that it has lost prestige. Rather the contrary

If by prestige you mean influence, and that is the definition that the dictionary gives for the word prestige-if you mean influence in matters pertaining to health in public affairs, in the actual shaping of the lives of people today, then the medical profession has not lost prestige forces of modern medicine are influencing the lives of every man, and woman and cluld-our whole public—to an extent far greater than at any other time in all listory and I can safely say to a greater extent than any other force operating in modern civilization

Present day civilization is made possible only by medical knowledge. This very city is able to exist only because of the influence of modern medicine Remove from New York or any other city the support provided by medicine and de moralization would follow

The public thinks of medicine as limited to the doctor, the hospital, and the dispensary, but medicine includes as well all the precantions that make the city of today the healthnest place that has ever been known, it includes such matters as food inspection, sewage disposal, water purification, health supervision, quarantine, and all the measures directed toward controlling and pre venting disease, as well as the doctor and the hos Urban civilization as we know it depends upon medical influence. That is prestige

But if you mean by prestige the acknowledged recognition, the kudos, that you feel and I feel should be accorded and shown to the men of a profession that has everted and is exerting the greatest force on the betterment of human life that the world has ever known, then, if that is what you mean by prestige, it has perhaps declined

And I fully appreciate the need for this very kind of prestige-not for the satisfaction of mere personal pride and personal gratification but as desirable in smoothing the way for medical progress and allowing the fuller display of medical benefits, with the correspondingly greater advantage to the public. If the art and science and practice of medicine are to continue to be of their full and enormous benefit, then the public must come to a realization of their responsibility for the contiminance of medicine, must acknowledge its prestige and give cooperation

If still further you have in mind as an ideal of the way the physician and his profession should be treated and revered, that attitude once extended to the cherished character of medicine, now growing obsolete and about whom wishful myths are developing-the old family doctor-a man who exerted a great influence on town life, who appeared as a paragon in medical matters, as an oracle on all subjects social and political, who was a father-confessor, who was a man after whom grateful mothers proudly named their offspring, and whose limitations were known only to his wife and the town druggist-if that is an ideal of prestige then it is a prestige of person ality and not of profession

If the modern physician is held in a regard less warm than that accorded to the old family doctor, if he is less revered as the leading citizen, then either the physician has changes, or the public, or And I believe it is both The reasons for the change in the public we can discuss in a mo ment, the reason for the change in the physician is, I believe, to be found in the subject which I have chosen for this talk-"The decline of medicine as an art "

A decline, a change, is always indicative of a past, some previous state Let us then examine the regard in which medicine has been held in the past, examine also the attitudes of the public, and likewise the benefits that, at each period, medicine has conferred upon the public

The definitions of the practice of nicdienie as given from the public's viewpoint are few and indefinite. But about 200 years ago a certain Mr. Ballow of London, a lawyer, made a now classic formulation of the practice of the past and of his day. It expresses the public regard of medicine in the early 18th century and its corresponding

prestige.

The story involves a certain Dr. Aikenside whose sole claim to distinction lies in the fact that he was the butt of Ballow's rancor. incident is included in Hawkins' Life of Jonson. Dr. Aikenside was an habitué of bar-rooms and of coffee houses. It was in Tom's Coffee House that he met Ballow. The two argued over the relative demerits of law and medicine, each holding the other's profession in the mutual disregard which is fairly common at all periods. The result of the discussion was a challenge to a duel. Both promptly repented of their impetuosity. The outcome was that Aikenside refused to meet Ballow in the morning; Ballow refused to meet Aikenside in the afternoon. A reconciliation eventually followed and on the occasion of the meeting at Tom's Coffee House, Ballow delivered his famous dictum of medicine. He coarsely inveighed against the profession of physic, laboring to prove it all an imposture. Aikenside protested. Ballow finally cut him short with, "Doctor, after all you have said, my opinion of the profession of physic is this—the ancients endeavored to make it a science and failed; the moderns to make it a trade and have succeeded."

But, let me say, that before the ancients endeavored to make it a science, medicine was a

religion. And always it has been an art.

Religion, trade, science, art, all of these things have had their influences in shaping medical practice. Elements of each one of them are found in the profession today. But throughout the span of history one has predominated, then another and another, each in turn coloring the practice of a period and each in turn arising as a product of the public of the time.

The average level of medical practice never gets far from the level of its public.

We talk of the public's regard of medicine, but in doing so we forget that the physician himself in any period is a product, is a part, of that same public. He has grown from it, his ideas and his ideals are colored by it. The state of the practice of medicine at any period reflects the state of the public; the public's attitude toward medicine reflects in turn precisely the regard in which the physician himself holds his own calling. When he regards it as an art or a religion he is venerated. When he holds it as a trade he is treated as a tradesman. When he holds it as a science he is treated as a scientist.

It would appear from the facts of history that the regard in which medicine is held at any period has nothing whatever to do with the benefits to be derived from it. Medicine has been held in highest veneration when it has had little or nothing of actual physical benefit to offer to the people; it has been held in the very lowest regard at a time when it has had more to offer. And today when it is not only offering, but is giving a vast amount, when it has become a very mainstay of modern civilization, it is received in some quarters if not with hostility at least with great indifference.

The regard in which medicine is held is an emotional state. Religion and art appeal to the emotions, trade and science do not. Modern scientific medicine appeals to reason; the public while admitting that medicine should be furthered, disease eliminated, life prolonged, remain aloof in the matter, for in the more or less sapient human beings that make up our public and our medical profession emotions are not yet dictated by reason.

Let us take a wide span of history and deal specifically with some periods in which one or another of the elements of medical practice has predominated. In each case let us see what the physician was like, what his profession gave to the public and what the public in return offered as social cooperation. I repeat to you that the regard, emotional regard, in which the physician held his own calling is precisely the regard in which the public held it and it is furthermore a gauge of the degree of public cooperation.

If we were to include quackery and cultism, and charlatanism in this discussion we should need to go clear back to the time of the primitive savage medicine man pounding a tom-tom to frighten away the spirits of disease, performing incantations to recall a wandering soul, and reciting charms to overcome the malign influences of an enemy. In short carrying out in various guises what we know today as faith-healing.

Quackery, or charlatanism, or cultism, is always medicine out of date. All the cultism of today is the discarded medical practice of the past and most of it is so far in the past that it goes into the primitive or savage state. If we brought from some South Sea Island or from the forests of Africa a native medicine man and allowed him to practice according to his native rites in our more or less civilized midst-and 1 have no doubt that he would be allowed so to practice in many of our states, if his foster and more up-to-date brethren in the legitimate profession of medicine could retain their cherished and exclusive privilege of signing the death certificates for his patients—such a man, a savage medicine man, would differ not at all in principles of practice, only in form, from the various cults of charlatanism already supported in our midst, whether they be metaphysical healing, back slapping, foot twisting, or patent medicine. Charlatanism is as atavistic as war-its existence proclaims the fact that civilization is only a veneer.

Scratch even the most cultured skin and you draw the blood of a savage. The charlatan does no actual physical good to his patients yet many people of our public hold him in veneration, the veneration of personal prestige. Those who submit to his ministrations have a stronger emotional feeling for him than for the scientific but frankly less artful physician.

Yet if education can contribute anything to man it should be in the control of the emotions by reason. Education as I conceive it is the training of the intellect to appreciate reason. Culture is the training of the emotions to respond in appreciation of art. The best educated man in only one generation removed from savagery and many cultured gentlemen who patronize charlatans are in reality only cultured savages who have an atavistic appreciation of primitive medicine.

Today the public is a generally cultured public and it has an influence on public affairs and upon medical affairs greater than at any other time in history. But the actions of a public are always destructive, never constructive. People tend to pull down everything to their average level. Advancement, construction is not made by great numbers, but by great individuals.

The primitive medicine man was a priest. The only element of primitive medicine that the medical profession has retained is the religious element still inculcated in our ethics and is found especially in the feelings of those men sincere in their love of their profession who believe that medicine today is the religion of man's salvation on earth, the most practical and the most humane philosophy that has ever been evolved.

As I said the primitive medicine man was a priest. And so when we come to those Grecian days prior to Hippocrates we find medicine in the hands of a religious organization, the priests of Æsculapius, the Grecian God of Healing who with his daughters Hygiea and Panacea were the idols of the ill. The profession was venerated. Its prestige was great. But what did medicine have to offer? Were the people healthy, did they live long, was infant mortality low, was there freedom from suffering, freedom from devastating epidemics? By no means. By modern standards those days which were the glory of Greece were pitifully disease-ridden, in comparison with modern conditions the people suffered frightfully, infant mortality was high, life was short. And what did those venerated doctors do to find the cause of disease, learn how to treat it, learn how They did very little. And why to control it? should they? They assumed no responsibility. The Gods brought disease. The Gods took it away. They might intercede with the Gods, but the responsibility was beyond their hands. they were venerated, respected, they had kudos. It cost the people very little to obtain medical

service and that service was worth precisely what they paid for it.

I may say parenthetically that this pre-Hippocratic medicine was subsidized medicine, strictly institutional and supported by the public, a variety that has been strongly advocated in recent years by the reports on the Cost of Medical Carc. It is peculiar how by the whirligig of time the old continually comes back as the new—we are now offered subsidized medicine with the will of the Gods replaced by the dictates of a board of lay executives.

Subsidized, institutionalized, medicine is based upon the conception that medicine is either an omnipotent religion or an exact science. Among the Greeks it was such a religion; among the moderns it is neither an omnipotent religion, nor an exact science.

It is unlikely that medicine will again become such a religion; when and if it does become an exact science then the highly trained and skilled physician will no longer be needed, but merely medical technicians such as now can carry out those aspects of medicine which have been reduced to a nearly exact science and are hence wholly impersonal as are some phases of sanitation.

The subsidized medicine of the ancient Greeks was broken down by a man whom we revere as the father of modern medicine, Hippoerates. He opened the way for the individual practicing physician.

His great contribution to medicine as a science was to take the burden of the responsibility for disease off the shoulders of the Gods and put it squarely upon the shoulders of man where it belongs. He said in effect that the Gods are not responsible for disease, but ignorance is. Man can learn to control disease only by gaining knowledge and putting that knowledge into force against disease. He thus supplied an incentive, a responsibility for bettering man's condition. And by whom was this responsibility assumed? Was it eagerly seized upon by the public who were to benefit? It was not. Did the public hail Hippocrates as the Messiah of man's salvation on earth? They did not. His simple, logical, honest principles appealed to reason, not to emotion. And furthermore did the physicians of the days of Hippocrates and in the subsequent centuries follow his rational procedure? They did not. Within the century medicine was a matter of contending theories and schools and dogmas. The physicians of those days, as of today, were a product of the public. In the six centuries following Hippocrates there was once or twice a flickering revival of true Hippocratic medicine. But civilization was declining, and as is always the case medicine declined with it. In the period following the fall of the Roman Empire, medicine reverted essentially to religious healing, but under the Christian regime it lacked the dignity that it had had under the pagan Grecian cult of Æsculapius.

It was not until the Renaissance and later with the revival of learning and the advancement of civilization that the responsibility enunciated by Hippocrates was finally assumed. And by whom then was it assumed? By the public to be benefited? No. It was carried on as it is now by the men of the medical profession who as a result are today giving to the public the healthiest period that the world has ever known. And this great end has been attained despite indifference or even opposition by a public who have refused to assume their share of responsibility for their own betterment.

Medical science has become the controlling influence in modern civilization, a fact recognized by a few lay historians of note but they are the The situation exceptions rather than the rule. was precisely defined by President A. Lawrence Lowell of Harvard in these words: He said: "It is hardly an exaggeration to summarize the history of 400 years by saying that the leading idea of a conquering nation in relation to the conguered was in 1600 to change their religion; in 1700 to change their laws; in 1800 to change their trade; in 1900 to change their drainage." And he continues, "May we not then say that on the prow of the conquering ship in these 400 years first stood the priest, then the lawyer, then the merchant, and finally the physician?"

A very pleasing tribute indeed to the medical profession, but if it be true that there stands to-day the physician on the prow of the ship of civilization, if it be true, and it is, that medicine of today is leading the people of the world to healthier and longer and better life, then why do not the public rejoice, and pay tribute with earnest cooperation to this great civilizing force?

There are two reasons. First, the public by and large do not know the facts—the history in the matter. Second the public do not feel the thrill of emotion that is necessary to bring into being a united and determined movement whether it be religious crusading, or patriotism of war, or a conquest to abolish disease. The public do not know; the public do not feel. And why? The first is a fault of our historians; the second a fault of our physicians.

Let us consider the histories first. The public obtain their knowledge of history in our schools and from general reading. Few of the men that write general histories have more than an inkling of the vastly important part that medicine has played in shaping civilization. Nevertheless medical history is world history. Some phase of medicine has been involved in every great historical event, but usually these medical aspects have been ignored or overlooked. Yet for everyone, medical history is probably more important than any other phase of history, for medical his-

tory discloses the forces which have made modern civilization possible. Few if any general historians tell of the actual health conditions of the people of any period; some touch upon the great epidemics such as the black death, but sanitation, health conditions, the diseases of the individual, they fail to record.

There is a whole history just in the statement of average lengths of life through the centuries—400 years ago the average length of life was about 8 years; 200 years ago it was 18 years; today it is 58 years. That is an aspect of medical advancement. Behind those figures for short length of life, of untimely death in the past, there is a story of suffering, sorrow, frustration, pathos that pales to insignificance all tales of war and politics, intrigue, and trade that fill the pages of our histories.

Let me make my charge against the general historian more specific. I shall deal with the physician in a moment. A few years ago H. G. Wells brought out his "Outline of History." Whether it was good history or bad I don't know, but it was widely read. I went through the book for any mention of medicine. I found one.one,—pertaining to the days of Hippocrates. The author said that the size of the Grecian cities was limited because of lack of knowledge of sanitation. In that one statement he raised the influence of medicine to a par with that of war, and politics, for the small size of the Athenian cities was the cause of their political and martial difficulties, in fact of their type of civilization. But having enunciated the fundamental truth almost parenthetically he at once reverted to the customary story of intrigues, and martial triumphs, and his general scolding of the great men of his story. Neither in that history nor in any other do the public have brought before them the great humanitarians and most humanitarians have been physicians. Before such men as Jenner with his vaccination, Pasteur and Koch who gave us sanitation, Lister who gave us asepsis and antisepsis, Walter Reed who gave us control of yellow fever, and Ross who led the way to wipe out malaria, and Long and Wells and Morton who gave us anesthesia—humanitarians all and before them I say Napoleon and Alexander, and Caesar sink to the insignificance of troublesome bullies.

The public of today do not know the conditions of life before medical science exerted its profound influence upon civilization. The average man is oblivious of the fact that pestilential diseases were once rampant, that suffering was vastly greater than today, and life infinitely shorter. He is oblivious of the fact that within a single generation all these unpleasant conditions could recur. He is concerned solely with the earnest desires for the elimination of the aches and pains and diseases which still afflict mankind. His atti-

tude too often is scornful, uncooperative. His attention is fixed not upon the triumples of medi-

cine, but instead upon its limitations

As I said the public does not know the facts and will only learn them when our histories have been altered. Furthermore even if they had the knowledge the public would not feel the emotional thrill that would engender a united effort, would lead to cooperation. And as I said before the emotion felt by the public is precisely the emotion felt by the physician. When he loves his profession gives his life and soul to it in faith, then and then only do the public feel the warmth of sympathy that makes for veneration of the profession. Only when medicine is a religion or an art is this feeling engendered. It is not called or a cold science.

Very briefly, just in passing, let us glance at medical practice in those days when it was preemmently a trade I should choose the time of There were some honorable, fine men of medicine in those days, there was the great Sydenham, but the general level of the profession was what lawyer Ballow defined it, a trade and a trade in ill repute. The common run of physicians were those whom Molicre satired in his plays when he took his needle from his tailor's trade and with it pricked the bubbles of human conceit Braggarts, empirics, formalists, trades Men without prestige The European physician ranked somewhere between the per-fumer and the hair dresser. There were exceptions as I said But surgery was essentially a calling of menials, medicine a resort of pompous impostures. Ten men indeed had any true love of their profession

And in the period in which the general his torian deals with the finances of Colbert, the politics of Richelien and Mazaran, the affairs of La Valliere and Montespin and the glorics of court life—what were the conditions of health of the people?

Let us choose one figure to show the prestige the influence, the benefits derived from the medicine of that period Take not a common citizen but a great king, the grand monarch, Louis XIV, renowned for his health and freedom from dis ease The medical complaints of royalty are al ways a commentary on the medical successes of any period, for a ruler commands the best medical attention. It King George of England today let us say developed smallpox or bubonic plague (the disease that kalled Petrarch's Laura) or diphtheria (George Washington died of that) or typhoid fever, or typhiis or malaria, or rabies or dysentery, or tuberculosis or even a toothache -diseases all preventable by modern medical knowledge-it would be a medical scandal. And set here are the more important diseases from which Louis XIV suffered

He was born with two teeth, so we are told, much to the discomfort of his wet nurse, he had smallpox when nine years old, a venereal infection a few years later, and then typhoid fever When 25 he contracted measles from the queen He was troubled with intestinal parasites, and certain courtiers in deference to his station have endowed him with a tapeworm of proportions to suit his royal mignificance and his royal appetite His teeth were bad and he was troubled continually with abscesses about them. He had overrhea At 44 he developed gout, and the following year dislocated his elbow by falling from his horse Three years later he developed a most personal complaint which interfered considerably with his royal magnificance and kept him for a time from sitting with comfort upon the royal He likewise had mularia, then a series of carbuncles His gout became worse, he was troubled with gravel. His arteries hardened. His legs became gangrenous He died

This is not the morbidity decord of a whole court that I have enumerated but of one individual the Grand Monarch. His successor Louis XV died of smallpox—one of the last important personages to succumb to this disease. This period of the time of Louis XIV was one, as I said, when the physicians, although able to give much more than did the priest of Assoulapius or even the doctors of Salerno, or yet the physicians at the brilliant heights of Arabic civilization, were looked down upon with contempt as pompous, shallow tradesmen, to be caricatured lampooned It is not a pleasant period of medical practice

I et us turn to the more pleasant one, to those days when medicine was supremely an art as an mocation of love I should choose the period of our own Revolutionary War and the years fol We could name such men as Shippen, lowing Rush, and Morgan as our examples The period in which they fixed was one when men's minds were turned to serious matters Devotion to principle was a characteristic of that day Pubhe minded, socially minded men devoted their services to the needs of their fellow men with an almost religious fervor, one of self-sacrifice Rush loved medicine, he believed in it with a patriotic fervor He was a product of the public of his time, a time when six medical men were signers of the Declaration of Independence Socially-minded men followed medicine as an outlet to give expression to their desire to help their fellow men They made an art of medicine They were great physicians The art of their profession was the ability to establish a confidence between physician and patient-an identification of common interest. They understood that the ill man or woman or child was for the time being not of normal mind was not a homo sapiens, and was not able to assume responsibility Sick people often care less for science than for

sympathy and human understanding. They want the physician to do something for them, something kindly. So long as the human mind in its full ramifications remains beyond an evaluation by scientific precision then medicine must remain an art. So long as medical practice involves the personal contact of physician and patient then it is the art of the physician that must establish the necessary bond of sympathy. And if in the interest of science rather than humanity this identification, this contact between patient and physician is lost then the public will in revolt turn to the charlatans who while doing nothing of physical benefit for their patients give them mental comfort. The patients of the charlatan may die, but they will die happier, supported to the last by confidence unfortunately born of ignorance.

The physician must be an artist; and an artist is a man whose talent, whose personality is suited to his calling. Benjamin Rush, Osler, all of our great practitioners have been men of outstanding personality. Few great scientists have been great physicians. Harvey who described the circulation of the blood was a bad therapist; Koch to whom we owe the conception of the bacterial cause of disease, gave up practice, Pasteur was not even a physician.

Yet the physician, realizing the inestimable value of these discoveries of science to the physical welfare of his patient, has too often tried to

make the sick room a laboratory.

During the last 80 years medical science has made amazing discoveries for betterment of health and for the prolongation of life. Preventive medicine has developed. The world has become healthier. No men have ever labored as hard to work themselves out of employment as have the physicians, for it has been the men of the medical profession who have used every effort to further preventive medicine,—the prevention rather than treatment of disease.

In the first flush of the triumphs of the application of science to medicine, it appeared that all the problems of medicine were to be answered and that medicine at last was destined to become as exact and impersonal as engineering. Our medical education changed; it adopted the precise methods of science. It built its structure on the laboratory as a foundation. Pre-medical education changed. For our medical schools we selected men who excelled in the laboratory sciences. We did not select men to go into medicine because of a driving desire to help mankind, socially minded men. In the medical schools the students were trained too often by great scientists and not by great practitioners. Attention centered almost exclusively upon the physical manifestations of disease. Consequently we have developed many bedside pathologists, interested in diagnosis for the sake of diagnosis but whose only contact with the patient is through the foot of rubber tubing on the end of a stethoscope.

Benjamin Rush was a great practitioner; to him his patients had both a body and a mind. He loved mankind. He loved medicine. It was he who said, "Medicine is my wife and science my mistress." And you may recall Oliver Wendell Holmes' comment. "Medicine may be his wife and science his mistress but it cannot be shown that the breach of the Seventh Commandment was of any advantage to the legitimate re-

cipient of his affections."

The physician of today is too often wedded to science. An artist is appreciated by the public he is revered; the scientist is not. Science to the American public for all that has been said of it is not a God; it is a servant; in becoming a scientist the physician has taken his stand with the chemist, the physicist, the engineer. And the chemist and the physicist, and the engineer for all of the great good they have done, and are doing to our civilization are not revered; they do not have the prestige which is so essential in medicine. The physician in becoming a scientist loses his prestige even though he does more for the actual benefit of his patients than would a man less scientific.

One can paraphrase the remark of the Frenchman who stood at Balaclava during the Crimean War and saw the heroic charge of the Light Brigade: "This is glorious but it is not war." Science is glorious, but it is not medicine.

THE MASTER IN THE HOUSE OF MEDICINE

By ALPHONSE M. SCHWITALLA, S.J., Ph.D.

Dean, St. Louis University School of Medicine

Delivered at the Annual Meeting of the Medical Society of the State of New York after the Annual Banquet on the evening of April 4, 1933, in the Hotel Waldorf-Astoria, New York City.

I.

Y title makes two assumptions, the first, that medicine still has a house and the second, that there is a master in the house whoever that master might be; assumptions both, which in the minds of some people, are rather violent and require some form of vindication.

For there are not a few, who priding themselves on their genius for the obvious, insist that medicine has long since forsaken its house and has walked perhaps in amnesic somnambulance into unaccustomed bypaths trespassing unconsciously upon the domain of the pure scientist, or the sociologist, or the economist, or the legal expert. There are those too, who insist somewhat equically, to be sure, and with not a little irony, that medicine, in its decadent senescence needs the stimulation of new ideas. They think it needs to be galvanized out of its over-stuffed settee where it has sunken in contented mediocrity watching some of its recent progeny flock about, possessing the house that was medicine's, somewhat like Sir Walter Vivian's visitors in Tennyson's "Princess." For Sir Walter

"All a summer's day
Gave his broad lawns until the set of sun
Up to the people; thither flock'd at noon
His tenants, wife and child, and thither half
The neighboring borough with their Institute,
Of which he was the patron."

"And there we saw Sir Walter where he stood, Before a tower of crimson holly-oaks,

A patron of some thirty charities, A pamphleteer on guano and on grain, A quarter-sessions chairman, abler noue;"

Of course this is a strange picture for those of us who still regard our mythological patron, Æsculapius, as the traditional personification of medicine; a splendid personification, for Æsculapius was the son of Apollo, the god of light and beauty and fertility and manly strength. Today, if we had to choose from the galaxy of gods, the one whom our present trends might best inspire us to choose as our patron, he would probably be the fleet-footed, wingéd-heeled and wingédcapped Hermes, Æsculapius' uncle, for his were the characteristics of inventiveness and versatility with fascination, trickery and cunning, a god, strange to say, not only of thieves, tradesmen and agriculturists but also of the pharmacologists and perhaps the biochemists if they liad them in those early mythological days.

Who now is the master in the house of medicine? The question is today rather interesting because it has been recently answered. answer has come as the Report of the Committee on the Costs of Medical Care. In its very first dictum under the section entitled "The Philosophy and the Intent of the Recommendations," the Committee tells us that the solution of the problem "of providing satisfactory medical service . will be of immense economic and social significance." Economics and sociology are here apparently nominated as masters in the house of medicine. In its first recommendation, the Committee nominates another candidate for this mastership "organization." Physicians, dentists, nurses, pharmacists, hospital officials, should all be organized. In the second recommendation, there occurs still another nomination for master of the house of medicine, the official health department around which, as a hub, so one may

casily understand the recommendation, the medical profession will wheel us all in our course to universal health. And in the third recommendation, there is still another nomination for this master of the house of medicine, the great god of Finance, through whom the purchase of medieal care on a group payment basis, on insurance plans and on taxation schemes is to be made more effective. And I regret to say, in recommendation four, another nominee appears, a weighty one, a dignified and ponderous one, the god of Centralized Control, for we are told that "the study, evaluation and coordination of medical services should be considered important functions for every state and local community." Surely, the recommendations of the Committee have put forth enough nominees for the master of the house of medicine. Each has a platform upon which to base his claim; each has a program which is to form a panacea for some, if not for all the ills from which the old master of the house is suffering; each is prepared to wage a campaigu. vigorous and virulent in vindication of his claim to dominance. A formidable array of worthy candidates-economics, sociology, organization, finance, official health agencies, public control. Where among all these is medicine itself? Who owns the house of medicine? And to whom has the house of medicine for centuries upon centuries belonged? Are we to forget the good old adage that "possession is nine-tenths of the law" and that other adage that "a man's home is his stronghold"? To vindicate the rights of medicine, just a tiny voice called the Minority Report was raised. And the Minority Report dared insist that perhaps the master in the house of medicine should still be considered medicine itself.

11.

In making these comments, I would not be understood as under-valuing in any sense the enormous contributions which the Committee on the Costs of Medical Care has made not only to medical economics but even more specifically to many other phases of medical practice; to our understanding of the social relations in medicine and of the public health significance of medical practice, to the inter-relationships between voluntary and official health agencies, to our grasp of the intricate inter-relationships between medicine and many and diverse public interests. On all of these classes of questions and perhaps on many others, the work of the Committee has accumulated vast masses of data which probably could have been assembled so effectively and completely by no other group possessing similar facilities in an equally short length of time. That all of this information is of enormous value in the cultural history of our nation can hardly be successfully denied by any thinking man. If, therefore, the final results of the Committee's activities have failed to commend themselves universally and particularly, if they have failed in impressing the medical profession as a whole, my explanation is only this that the Committee members were carried away by an overwhelming sense of responsibility to the public at large, a sense of responsibility which obscured the clear vision of the means by which the health betterment of that public could be best safe-guarded, namely, the progressive and ever-accelerated development of the one profession to which is entrusted in our scheme of things, the maintenance of the public's health and its restoration to health after sickness.

The Committee understood too well its sociological, its economic, its organizational, its financial and similar problems, but understood too little the character of its medical problem. It saw the masses and forgot the individual who makes up the masses. It saw the distant vision but it saw not the single man who stood close at hand. Enamoured of the future vision, it was blind to the near reality. Carried away by long distance planning, it forgot that such planning is conditioned upon the satisfaction of immediate needs. The far-off mountain seemed so near that the chasm in the foreground was completely overlooked. All this is my view of the Committee's work. It made nominations for the dominance of the house of medicine and forgot that medicine is still and must continue ever to be master in its own house.

III.

Let me single out for special discussion the strategies and sorties of three separate challengers of medicine to the ownership of its house. All three challengers are generals in the socio-economic-political army each leading his separate division to lend force to his challenge.

The first of these challengers might be called Efficient Mass Production. It must be admitted that he has many seemingly convincing claims to the ownership of medicine's house. The statistical data amassed by the Committee proves perhaps to demonstration that the people need a substantially larger volume of medical service than they now utilize; that modern public health service needs to be extended to a greater percentage of the people and to hitherto uncared for areas; that a geographical redistribution of practitioners and agencies must be effected.

How does the Committee propose to meet these needs? The majority of the Committee recommends that medical service should be furnished by organized groups, these groups to be organized around a hospital for rendering complete home, office and hospital care. This being effected, the community possesses what the Committee itself calls its "most fundamental specific proposal" (page 110), its own community medical center. The Committee suggests the intensive develop-

ment of medical service, the more effective utilization of subsidiary personnel, the expansion of the private group clinic, of the pay clinic and of middle rate hospital service, organized nursing service, and of clinics controlled by county medical societies.

Are these recommendations a real answer to the needs? They rest, they seem to me, upon a false assumption that mass production can be effected in medical practice just as it can in indus-They lose sight of the differences between human beings and machines, between the physician and the mechanic. We may teach a mechanic to assemble with ever-increasing efficient speed the parts of an automobile and to fit each such part into a pre-destined and pre-planned place; we cannot teach the physician to treat the diseased organs of one human being as he would the corresponding parts of another human being even under what are ostensibly the same conditions. Symptomatology was at one time thought to be indicative of a disease; today it has become indicative of an individual's characteristics and constitution. No matter how many patients he has, if the individual doctor fails to treat each of these cases with as much care approximately and with as strong a sense of responsibility as he would have if this were the only patient under his care, the physician has fallen short of the legitimate expectancy of his clientele.

The fundamental reason why the individual patient cannot and must not be treated as a member of a large group is because of his uniqueness. Let us not forget our fundamental biology. Biochemistry, genetics, physiology, pharmacology, the science of immunity, all these and many others of the fundamental and the clinical sciences are insisting with constantly increasing emphasis and with reliance upon rapidly amassing evidence not upon what used to be called the clinical disease entities but rather upon the individuality of each We have learnt to lay less stress upon similarities and more stress upon dissimilarities. In medical practice the laisser-faire adage that "exceptions prove the rule" finds no application; rather does medicine say, when there are exceptions there is no rule. Many a page of biological history has been turned since the day when Huxley could insist that the protoplasm of the cow and the protoplasm of the grass devoured by the cow are the same protoplasm. Our research laboratories have shown us that we can no longer think of one uniform basis of life but that we must look for individual differences in protoplasm when genus is compared with genus, species with species, sex with sex, individual with individual, organs of one individual with the corresponding organs of another individual, yes even, not to labor the point too much, when one cell is compared with its contiguous cell in the same tissues. Medicine has derived from this viewpoint

the principles for its greatest conquests. We have learnt to understand constitution, allergy, heredity, hormonal control, the so-called idiosyncracies, all these and other phases of medicine too numerous to mention are each an emphatic insistence upon the differentiation of each of us among our kind.

How then in the face of all of this can we still insist upon mass production and efficiency in medical practice? All that we have learnt recently is a plea for the individual care of the individual patient by the individual physician. Only the latter can synthesize effectively and to the patient's best interests the pieces of the complicated jig-saw puzzle that are supplied to him through his stethoscope and microscope, through his test tube and stop watch, through his eye and ear and To be sure, there are limitations to this insistence upon individual practice but when the exigencies of modern medicine and the public's needs demand, let us grudgingly rather than gladly yield to the hurry and scurry, the scramble and scuttle of wholesale practice. It is one thing to practice wholesale medicine through need and pressure with regrets for one's neglected ideals, and it is quite a different thing to convert wholesale medicine into a routine which progressively metamorphoses into an established objective. can also understand that under certain carefully controlled conditions with broadly trained, widely visioned leadership and in an environment of cautious and scientific clinical thinking, the mass practice of medicine can be made to yield results of outstanding value. But I submit that even then those results are achieved not so much through mass practice but rather through the superior leadership in such a group as well as to its superior facilities. The Romans had a proverb which can readily be misunderstood but which nevertheless contained many a germ of many a great thought "quod licet Jovi non licet bovi." We know that the same words in the mouth of poet and peasant have a different meaning, the same action of banker and baker a different significance. The efficacy of medical centers does not rest in the institution as a medical center but it rests in the mental and material soil in which it is planted, in the administrative offices where presides the controlling mind and heart, in the laboratory where the chemist, the pathologist and the clinical microscopist sees or sees not the facts that are revealed to the understanding eye. To recommend the development of medical centers and to ignore a recommendation for the installation of those within the medical centers who alone can give them meaning and life, is to me nothing more than to build caskets for our defunct ideals.

There are many other considerations which might well enter into the story of mass production's onslaught upon the mastery of the house of medicine. Let me pass them over with but a

brief mention. I can think of mass practice of medicine as advocated by the Committee for general adoption as nothing else than merely yielding to the present needs at the sacrifice of future good. I can think of it only as offering a prognosis of progressive deterioration in ideals, as a shield for the less able, the less industrious, the more mercenary in medicine, so that they might hide behind the men of solid achievement, of continued application and unselfish dedication. us not lose sight of human nature. Of all the professions, medicine is perhaps the one in which insincerity is most promptly uncovered; perhaps the one in which the blackness of incompetence and quackery is most easily dispelled by the bright light of science; perhaps the one in which the stumbling of the stupid is made more easily apparent. Yet with all this, medical men are still human and as long as humans are, the easiest way will be for all too many the way of choice.

Mass practice must never dispossess medicine

from its ownership of its house.

IV.

The second of these challengers to the ownership of the house of medicine is Organization. All through the Report and the many other studies which lead up to its final formulations. thoughts are stressed that our difficulty is not so much with the number of individuals concerned directly or indirectly with practice of medicine, but rather with the lack of coordination of effort in this vast personnel of more than a million. All through the keynote is sounded that it is not so much inadequate expenditure as it is ill-advised expenditure which has brought our needs to unbearable urgency. And so the shibboleth echoes through the recommendations. "Organize everybody and everything; organize the doctors, the dentists, the nurses, the social workers, the pharmacists, the hospital officials, the midwives, the hygienists; organize resources—the buildings and grounds, the laboratories and admission offices, the hospital and social centers, the outpatient cubicles and the in-patient beds; organize the funds-donations and dues, patients' payments and community contributions. Organize the community itself for better health care. Break down the barriers of race and creed of national and political affiliation.'

Now it cannot be denied that if the voice of some great dictator were to ring with the force of Gabriel's trumpet through the hills and vales and plains of the land, much might be accomplished through organization. And yet, like the faint trilling of the cardinal on a late spring sunny day above the roar of Niagara's falls comes the plea of the Minority, whispered 'through the thunderous boom of the Majority for the restoration of the general practitioner to the central place in medical practice. With what timidity the

poor Minority must have written its fourth recommendation. Surely, they must have felt as sheepish and apologetic as if they were recommending the substitution of a horse and buggy for the modern palace on rubber tires. They could not but have felt as timid as if they had called for side burns, Prince Albert and silk hat as substitutes for the dapper toggery of the just doctorated medico. And yet, the general practitioner owned and some of us think still owns, the house of medicine.

First of all, I cannot bend my good Catholic knees before the god of Organization. It is true we have long since celebrated his apotheosis, but something must have happened when he reached Today, like Vulcan when he was shown the door and came tumbling down, organization limps. Somehow we have lost confidence in his omnipotence and perhaps some of us are even sacrilegious enough to deny him divine honors. The catastrophes of the last few months have made scoffing skeptics of us all. And now we want to organize medicine and to organize it not as biology teaches. All true organization must be effected through the pressure of internal forces through which the organism is maintained and not through the coercive pressure of external forces which molds inert matter alone into forms and shapes. I contend that the profession of medicine is not as yet inert matter; it is still a living, vibrant group of men who know their own minds and hearts, their own ambitions and longings, their own capacities and achievements. Yes, I too desire the more efficient organization of medicine but I want that organization to come not from without but from within the profession. I want the profession to differentiate itself to progress to ever more refined forms of specialism ut all this in response to the superior needs of the profession working out its own destiny for the betterment of its own service to a community standing in need of that service and not through the pressure of alien forces that would mold it like passive clay into mere caricatures of the sublime form which it has set as the goal of its own development. Again, I say, let us not forget our biology. Organization from within never destroys the morphological and physiological traits of the developing organism but brings them rather to their termination. Organization from without restricts, contracts or expands here and there in response to pressure variations and the resultant may be a misshapen mass. Medicine as we have it today in our country has fulfilled a reat destiny. It is all but unintelligible that totay when medicine is celebrating day after day rogressively greater triumphs and is giving proressively more convincing evidence of its inteor life and is even in the face of the restrictions id privations of the last few years, humbly orying in the fact that it alone among the mainr

forces and human society has preserved the he record of the nation at a level of excellence n before achieved, we should be clamoring for r organization. It seems little short of blind to facts that just when medicine has best st that it can use its liberty and depends to a d equalled perhaps in terms of service by no of the professions dealing with man's ph life, we should attempt to shackle its freed

The question clearly is this, shall the mof the house of medicine be entrusted to a dividual practitioner or to a sort of house mittee which might be called for convergence of the Majority and the Minority group to satisfiedly endorse the maintenance of the personal field of the personal material what different meanings the groups have discovered in this personal reship. Old Aesop was right when he said great deal depends whether the song, the may be the same, comes from the throat o ing or of crow. Somewhere in the definit a satisfactory medical program the Repc us that (page 39)

"preservation of a personal relations! tween patient and physician is an essent ment in safeguarding the quality of sh practice."

Aentele.

Then the Committee goes on to my the inc cal practice and suggests two precise and practice as essentially embodying this prelationship. First, the safeguarding as in the privileged communications between and physician and secondly, the continued responsibility between patient and physicistates expressly

"the business relation between physicipatient is not considered a necessary j the personal relation."

As if to strengthen this position a few para further down the Committee again comes the question

"there is nothing in any way mysterious relation between a patient and a physicia the therapeutic side it is capable of comp jective analysis. As to those phase and not strictly medical, it is of plasm. C satisfactory human relations us that w do mutual patience, symposis of and confidence." (Page 4 dual different with

5,

physician on the part of the patient, and mutual regard on the part of each for the other which cause the patient to disclose for the purpose of diagnosis and treatment the most private and confidential information concerning himself and his surroundings when necessary for proper diagnosis and treatment. The character and personality of the physician is a major factor in its development and in process of time and continued contact as patient and physician a friendship and intimacy develop that assumes priestly characteristics on the part of the physician-the characteristics of the confidant and adviser in the most intimate personal and family relationships. All phases of personal and family life are at times closely related to the diagnosis and care of an individual's condition, and economic and financial conditions are often as important in diagnosis and care as physical or mental abnormalities. It is an individual relationship, the product of character and personality and cannot be transferred to a group or fostered by group practice."

Again let us remember our fundamentals in Biology. We have heard it stressed ever so often in the days of our undergraduate courses that the organism's reactions at any one time are the product of internal and external forces. Not one added to the other nor one multiplied by the other but one set of forces integrated into the other in the sense in which calculus perhaps teaches us to integrate. There is this strange fact in the interplay between organic and environmental forces, that, as the organism reacts to an extrinsic force, it itself changes and forms not the same old, but in many respects a completely new source of new reactions in the second instant of an extrinsic force's influence. There is progressive change in the organism during the separate and separable instants of the organism's reactions. If we have learned to view disease and illness from this viewpoint we see the fundamental correctness of the analogy I am here suggesting. It is not enough for the physician or the social worker assisting the physician to have once determined the external environment of the patient, to have tabulated these and classified those conditions, but all through the patient's illness the progressive changes under the stimulation of the new environmental factors must be studied, not only with relation to the pre-siekness condition of the patient but also with relation to the gradual organie modifications. If I should eare to admit, for the sake of argument, that much of this is largely theoretical and difficult to reduce to practice, I still maintain that it is a fundamentally sound conception and one which consciously or uneonsciously the physician who is in close, intimate touch with his ease not only understands but actually uses. The modifiability of the patient's

behavior under medication, the antagonistic or synergistic action of drugs, the psychological interplay between patient and physician, between nurse and physician, between patient-nurse-hospital personnel and physician, all these, and many other examples that may be offered, illustrate the principle that during the therapcutic processes not only environmental conditions, but the organism itself is changing and is being made the center of a constantly shifting and changing set of reactions. To my mind the Minority has more closely grasped this very fundamental thought when it

"that all phases of personal and family life are at times significant in therapeutics"

and I believe the Majority has profoundly failed in its formulation when it insists that on the therapeutic side the relationship between patient and physician is susceptible of completely objective analysis. There are more intangibles in sickness than there are in health and these intangibles become progressively multiplied the more serious the patient's condition becomes, to reach a climax of complexity as the final moments of life are approached, even after the physician has explicitly or implicitly pronounced his inability to cope with the disease. I for one should not want to be responsible for the effect on the nation if this phase of medical practice is minimized nor should I desire to be responsible for the blurring of that idealism in the life of the physician or in darkening of the public's attitude towards it which would result from making light in any way of the sanctity, and if need be even the mysteriousness of that relationship between the sick man and his doctor.

If some one wishes to tell me that I am confusing two ideas in this presentation, namely, that I am assuming that personal relationship can be maintained only in the face of the general practitioner's place in medical practice, I have many reasons ready for my position, some debatable and, to my way of thinking, some entirely undebatable. Only one do I wish here to single out and that is the testimony of the Report itself. have called attention to the fact that both the Majority and the Minority insist upon the maintenance of personal relationship. The Minority draws from that principle the conclusion that, therefore, the general practitioner must be returned to his central place in medical practice. The Majority was able to use the principle in its advocacy of some form of group practice only by attenuating the meaning of that relationship and giving it a definition which, while not invalidating the logic of the argument, still negatives, as I see it, all that we have been accustomed to think of when we insist upon the importance of the personal relationship between physician and patient.

If now we insist that it is impossible under the present conditions in the practice of medicine to restore the general practitioner to his place of honor even if we wish to do so, my answer is plainly this, that unless we do so we must be prepared for a re-definition of the practice of medicine from sources that are not medical. We must be prepared to give up what we have hitherto understood by the term medicine and we must accept in its place all the inferences and correlaries that will grow from the conception of group prac-The Minority has suggested that the general practitioner can be restored to his place even in the face of the present complexities of diagnosis and therapeutics. It recommends not only intensively better preparation for the medical man and a growing sense of responsibility among medical educators for supplying the needs of the nation, but particularly does it call attention to the fact that in our medical curricula the stress must be laid rather upon the practice of medicine than upon the practice of specialty, rather upon the organism as a whole than upon its histological, or physiological, or biochemical or bacteriological This does not deny the validity and dignity and the deep significance to the nation's health of progressive specialization but, as I have already said, it is one thing for specialization to emerge from medicine's epigenetic self-determination, one thing for specialization to be the outgrowth of recognized needs in practice, and quite a different thing for specialization to be the resultant of extrinsic coercive forces or merely the pro forma denomination adopted to make the letterhead of group clinics more impressive to the public.

Who is master in the house of medicine? I hope and pray that the general practitioner with all his faults and all his shortcomings and all his limitations may still continue as the central dominating figure in the house of medicine.

V.

Ringing through the Committee's discussions like an obligato in a minor key runs the motif that builds itself up slowly but surely into a haunting spectre and that haunting spectre is the tremendous charge that the practice of medicine as heretofore in use is out of date. And oh, what more terrible thing could be said of any social factor today than that it is hoary haired and senescent. And against the background of this charge there emerges the third claimant to the mastery of the house of medicine, sprightly, spruced-up, spick and span, the claimant of professional evolution. Commentators on the Majority Report have stressed so often the thought, that they advocate, to be sure, not radical revolution but only progressive evolution. Perhaps our sympathies go out more to these claims for the mastery of the house of medicine than to

the others because our sympathies go out to youth but perhaps also wisdom of age might speak just a word of caution, even in this day when we are living in the age of the young man.

The argument, I suppose, should run something like this. We have passed from an age of superindividualistic to an age of sociological thinking. We have by dint of common effort succeeded in bringing the sociological viewpoint into legislation, into commerce, into international relations into labor and trades, into school and churches Through extensive propaganda, we have succeeded in all of these human endeavors to substitute a consideration for the masses instead of the old considerations for the individual. Why should we leave the profession of medicine out of this universal social flood, why should medicine stay behind in this forward movement?

On the face of it there is something intensely attractive in such a formulation. I submit, however, that there are considerations which will show that medicine cannot wholeheartedly and completely participate in such a drift if it desires to remain true to itself. I cannot accept the principle that a something is desirable just because it is new. I am still enamored of the Coliseum and of the pyramids and of the monuments of Assyrian culture and even of the art of the cave man in the Pyrenees. I have a suspicion that some of the things of life which I most value were just as valuable to primitive man, and so I am not over-impressed by the claim that medicine must have a new viewpoint, an eye to the future. Of course, neither am I blind to the fact that we are living in the year 1933 and that we are expecting to plan for at least a year or two more in our educational program in medicine, but it is one thing to say this and quite a different thing to plan for 1980 when between then and now there still intervene a few years. Haven't we become just a little fed up on this long distance planning and on directing the nation's course for half a century? We have even become a little skeptical about the five-year programs both on the international as well as upon national levels.

Now of course we all want to be modern but are we going to forget that the future is a child of the past, are we going to forget that the true view of history teaches us that history is a prophecy rather than merely a record? There prophecy rather than merely a record? are certain phases of life that must run on continuously and uninterruptedly through human experience, and fundamental principles cannot in any true evolution be completely ignored. I know we are living in a sociological era, in an era when economic factors and sociological factors have developed a significance which perhaps they have never had before. I know, too, that sociological and economic thinking have found their way into medicine. With all of this I am in complete and hearty accord. I hope all this may continue.

Let us again examine the situation briefly from

the viewpoint of what seems to be incontrovertible principles. A profession like an organism must adapt itself to progressive changes. Let us note however, that the first and foremost requirement for adaptation is the organism's or the profes sion's self preservation. Change is significant buly if the organism remuns If the organism does not adapt itself to changing environment it will destroy itself. But note too, and here is the point upon which I am throwing the cuiphasis, if the organism over adapts itself it will also destroy itself. Adaptation does not mean a merging of the organism with its environment Essentially it means the maintenance of a measure of isolation the maintenance of individualizing traits and characteristics, the maintenance of internal factors which must not so yield to extrinsic factors that they are completely neutralized. On the basis of this analysis I insist that medicine is not sociology and medicine is not economics and medicine is not organizational efficiency and that the future of medicine, the real progressive evolution of medicine, demands that medicine be allowed to develop as medicine and not as merely an adminet to social science I am not one of those who insist upon pigeon holing into separate compartments the diverse and varied interests of mankind Human interests must not be kept in hermetically sealed compartments. But recognizing all of this we must still insist that neither are we furthering progress by obliterating the individuality and the differentiating characteristics of the many voca tions and avocations which concern themselves with the contrasting phases of life

Pursuing this thought a little farther I should like to insist that medicine must become progres sively conscious if necessary emphatically conscious in the face of popular clamor of its own intrinsic dignity. It has a character to maintain If "noblese oblige" is still the watchword it was then the medical man had better not make himself the tool of an insurance agency, liad better not make himself an under paid servant of a policy holder had better not make himself merely the scribe to whom a financial power dictates what he is to write into the blank spaces of an accident Not in that direction lies progress no matter how much we clamor that this day is the dry of social thinking and financial remedies and corporate relief I might add paragraph upon paragraph on this point. Let me briefly summar ize a few of the views which have grown out of the principles advocated by the Minority some of them clearly expressed, others barely implied An insurance plan which takes away the freedom of the physician in his practice of medicine and substitutes financial expediency for medical policy is not good medicine and I helieve, is not even good insurance An insurance policy which takes medicine out of the central place in relation to the patient and relegates the medical practitioner

to the periphery of interest leaving the premium collector at the hub of the wheel is bound, I think sooner or later to throw the medical man nff of the which altogether and leave the financial agent in charge. Plans for part or deferred payments which substitute financial need for the patient's medical need, which elevate financial administratinn to the commanding position in place of medical care, are to me not signs of progressive evolution and thinking in terms of un to the-minute values but they are to me symptoms of medical When such plans and schemes are devolution in force you may be purchasing something for your policy holder but you are not purchasing adequate medical care. I can concede that under certain rather well defined circumstances some form of corporate practice in medicine or corporate payment for medical service is clearly indicated. It is one thing to let such plans develop in response to local or general needs is a different thing to elevate such a situation to the dignity of national policies

And anyway, is economics after all so much of a god to be worshipped? There are other values in life besides the dollar sign and I have a suspieion that they are just as much up to date. Money after all is only a symbol of barter We may barter away through money exchange some of the things which even money later on cannot buy Let the idealism the self-respect of the medical profession its quasi sacred character, the passion for excellence be traitorously sold for silver and you may well find yourself the insti gator of a crucifixion not merely of the profession but also of the public's welfare not of those who must by virtue of our depend ence upon public opinion allow themselves to be wafted hither and thither by the ever veering We are rather the breath of public opinion leaders and teachers of public opinion. It is not for us to yield but to lead to educate to idealize. our eyes are not to be cast down on the ground our feet, it is true, must rest on solid ground lest we drift away into aethereal regions of impracticality but our eyes must be up-lifted and our hands must be raised not to point out the paths where the masses will tread without us but those paths of higher achievement which mean progresswelv higher and nobler things in life

VI

And so gentlemen I have put before you the claims of three pretenders I believe personally that their claims are weak. I believe that their following is half hearted that the resources be hind them are inadequate to cope with the responsibility which they foolishly and ignorantly desire to assume. And I for one am prepared to vote them out of the mastery of the house of medicine and to leave medicine in control of its house.

THE X-RAY AS AN AID IN THE EARLY RECOGNITION OF SERIOUS DISEASE. OF THE COLON*

By WM. H. STEWART, M.D., AND H. EARL ILLICK, M.D., NEW YORK, N. Y.

IFFERENTIAL diagnosis in organic disease of the colon has always been hazardous when based upon the clinical history and physical findings alone. In recent years the x-ray has made a distinct contribution in the field of diagnostic endeavor enabling one to demonstrate the exact lesion which is responsible for the symptoms.

The study of pathology in the colon by means of the x-ray may be accomplished by several different methods, the most familiar being the gastro-intestinal series following a barium meal. In this type of examination the diagnostic emphasis is placed upon the stomach, which is generally examined serially, the colon being visualized only incompletely at the various hour examinations.

When colon pathology is suspected, the lesion is usually best demonstrated by means of a barium clysma. The entire colon is thus outlined and may be studied as it fills, at full distention and after evacuation. Each stage yields important informa-

tion and requires separate study.

- (1) Filling the colon: sigmoid lesions can best be observed when only the pelvic colon contains barium and before loops of the ileum fill by backflow overshadowing the sigmoid. By turning the patient, the most favorable oblique angle to view the sigmoid may be obtained during fluoroscopy and radiographs made. About one pint of the barium solution is necessary so that the rectum, sigmoid and lower descending only are filled.
- (2) At full distention: the lesion may be better demonstrated especially if in the upper colon. Fully distended loops of colon may overlie and cover up the lesion unless carefully palpated under the fluoroscopic screen.
- (3) After evacuation: is many times a decisive part of the examination. The retained barium scattered through the colon in a definite mucosal pattern renders detection of any infiltration of the wall quite easy. If the colon remains well filled after the first defecation, only the rectum and sigmoid emptying, repeated examinations must be made after several attempts at evacuation; the final roentgenogram should demonstrate the mucosal pattern of the colonic wall, especially in any areas suggestive of disease on the other roentgenograms.

Insufflation of the partially filled colon after defecation of all but traces of barium is of value in outlying polypi, tumors and other filling defects of the lumen of the colon.

A helpful manner of examining the colon in selected cases is to have a pint of barium solution given on the ward and expelled before the patient comes for x-ray. The mucosal folds of the colonic wall are often well outlined on the roentgenograms by this procedure and then a routine clysma with full distention or insufflation performed as indicated.

When the sigmoid is especially redundant, distending the urinary bladder with sterile physiological salt solution may aid in outlining a lesion of the sigmoid by displacing the loops into a more

advantageous position.

As can be readily understood from the above brief consideration of the technical procedures, successful roentgenographic examination of the colon dare not be standardized but requires individual and varied procedure to best demonstrate the lesion.

Cancer and other serious disease of the colon may give slight if any clinical findings and this is true in about half of the cases. The history is Any change in bowel vague and misleading. habit, any colonic dysfunction which persists and becomes progressively worse for a period of a few weeks deserves careful roentgen study before it is to be treated as due to functional causes. The difficulty in early diagnosis of cancer of the colon is summarized by the fact that three-fourths of the cases are already inoperable when the diagnosis is made. More than two-thirds of cases of cancer of the colon involve the recto-sigmoid which is the next most common site for cancer of the intestinal tract to that of the pylorus.

A routine clysma may fail to clearly outline a very definite lesion of the colon especially in the sigmoid. There is more misinterpretation in lesions of the sigmoid than anywhere else in the intestinal tract due to a number of factors—the lower colon is freely movable; it is usually redundant; generally coils on itself; is deeply situated just in front of the sacrum and surrounded by the pelvic walls so that it is difficult to directly palpate or even satisfactorily visualize. The back flow of the clysma into the terminal ileum produces overlapping shadows which cover up the sigmoid and makes detection of incompletely obstructive lesions almost impossible.

In our experience the most satisfactory solution of these difficulties depends upon a special examination when only the pelvic colon contains barium, a procedure which will be explained again in connection with the lantern slides.

Finally, some observations concerning differentiation of serious lesions of the colon will be attempted.

Tuberculous involvement of the intestinal tract is best demonstrated with the meal by mouth and is characterized by a filling defect and retention of the barium in the distal small intestine and

^{*}Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., on May 24, 1932,

with hypermotility in the proximal colon so that the ileo cecal region fills poorly if it becomes filled

Diverticuli produce sacculated outpouchings from the lumen of the colon which retains barrum and are best demonstrated in the 24-hour films after the meal by mouth. If a clysma is given, the greatest number of diverticuli are usually shown the day following the administration of the clysma. In an early or acute stage of diverticulitis, the colon outline may only be seriated with narrowing of the lumen and spasm, this involvement being most common in the sigmoid and with no pouches or only one or two distinguishable At times the sacculations may occur between the layers of the wall of the colon and not be visible outside the lumen, rupture of the diverticuli may take place into the wall of the colon and a palpable tumor be produced. The filling defect may occasionally be indistinguishable from malignant mvolvement

Benign tumors are sometimes found—lipoma, adeno fibroma and others, the essential characteristics being a filling defect within the lumen of the colon which is constant on all examinations, the shadow often being rounded and having slightly movability if pedunculated

Polypi produce a sago-like or lcopard-skin appearance, being lest demonstrated after insufflation of the colon following defectation. These cases are potentially malignant and the diagnosis is of importance for that reason.

Granuloma may produce narrowing and deformity of a long section of the bowel. We have had two proven eases recently, one of the eccum and one of the sigmoid. The filling defect is enormous and the tumor may appear imoperable when exposed, however, no cancer or other specific disease is found nucroscopically. Roentgen treatment is musually efficacious, the tumor completely disappearing very quickly.

In malignant involvement of the typical "nap-kin-ring" type there is an annular construction deforming both sides of the wall of the colon. There is a central canal with out micosal folds being distinguishable which is worm-like as a rule and has irregular edges. This canalization is typical of malignant involvement. There may be dilatation of the colon proximal to this lesson. Other types of malignancy produce narrowing of the outline of the colon, encroachment of the walf on only one side, or finger-printing. If micosal folds can be distinguished in the involved area malignancy is very unlikely.

OPPORTUNITIES IN MEDICAL ECONOMICS

Physicians now have an unprecedented opportunity to develop a practical system of medical economics; in fact it is forced upon them by statutes of New York State. law and the decisions of the courts have recognized four necessities of life,-food, clothing, shelter, and health. The first three can be produced and distributed by amateurs; but health service and medical treatment can be given by physicians only.

The State has assumed the burden of supplving medical service to the destitute; but the State must purchase it from those who The doctor who donates his have it to sell. services to the destitute, makes a gift to the taxpayers rather than to the poor. It is for the doctors to agree with the government officials as to what shall be a fair price for their services to the destitute. The doctors will be generous, and the State just and fair.

TEMPORARY EMERGENCY RELIEF ADMINISTRATION

The committee Dr James N Vinder Veer, Dr Albert G Swift, Dr Hyzer W Jones, and Dr Joseph S Lawrence, appointed to consider with the Temporary Emergency Relief Administration may promote health work among those receiving home relief, has received some reports from county societies indicating that the committee's work has been helpful

Quite a number of questions have been asked regarding certain details of the Administration which have been answered by correspondence, or by members of the committee attending confer-

ences of the county societies

It is to be hoped that all physicians will take scriously the effort that is being inade and assist the committee by keeping it informed as to how the law is being administered in their particular counties. It is of first importance that every county society should have appointed a Special Committee for this purpose, others have designated the Public Relations Committee which seems to be a logical designation, and again others have authorized their Committee on Medical Economics. A satisfactory administration of this law can only be accomplished by whole-hearted cooperation of physicians and social workers.

The commissioner of public welfare whether of the town or the county, is under the law responsible for the welfare which includes medi-

cil service of those persons who cannot supply the same service for themselves. The quality and quantity of service he may determine according to the amount of money at his disposal. The physicians, however, have but one quality of service to render, and during this present condition, which may be considered a period of emergency, it is recommended in making the charges for their service they offer, temporarily, a reduction up to thirty three and one-third per cent from their regular fees.

The Temporary Emergency Relief Administration has established a working basis with the several commissioners upon which it will refund to commissioners who work according to its program forty per cent of the amount expended in providing incdical service for home relief. A statement of that appeared in the Health News of the State Department of Health some time ago and in some instances was misinterpreted as being a statement of a schedule of fees which the welfare commissioner should employ in paying for inedical service. A correction of this impression has later appeared in the Health News

If your county society has not already taken active steps to bring about a satisfactory administration of this law in your county we hope that it will do so in the very near future. If the State Society Committee can be of any assistance, please

make use of its advice

LOOKING BACKWARD

This Journal Twenty five Years Ago

Health Endowments This Journal of May, 1908 discussed the prospects of obtaining endowments for the promotion of health in the following editorial comment on the prospect that Mr Carnegie will give \$400,000,000 for public health work.

'While thus far there have been but comparatively small beginnings in the way of donations from wealthy men for the advancement of medical science, there is no doubt but that the immense value of such work will soon be so widely appreciated that endowments for its aid will rival

those which for a quarter of a century past have been bestowed upon colleges and hospitals. Not withstanding the high position to which medical knowledge and its application have attained, there is at the present time, as never before a need for financial aid in the advancement of this work. The great possibilities of medical science and the mediculable benefits which he all but within the grasp of humanity, wanting only adequate aid for their accomplishment and full realization should appeal to every philanthropist who can be confronted with the facts."

MEDICAL PROGRESS

Forcible Nasal Inspiration.—Having been called to see a patient because of bleeding on the sixth day after a tonsillectomy had been performed James Dundas-Grant found that the bleeding was not coming from the tonsillar bed, but from the left half of the nasopharynx, from which a small amount of adenoid tissue had been removed. After cleansing the nose and throat with peroxide of hydrogen, he instructed the patient to make several forcible nasal inspirations, each followed by the gentlest expiration through The hemorrhage diminished very the mouth. perceptibly. The blood-stilling action of the forcible inspiration depends on the fact that the powerful expansion of the chest leads to a dilatation of the hollow organs in proportion to the degree of their softness. The right cavities of the heart are the most dilated, but the general dilatation leads to the blood being sucked into the thorax and a consequent lowering of pressure in the peripheral vessels, including those of the nose and nasopharynx. Among other means of checking hemorrhage from the nose or throat, one which will be found most useful is the clinical application of J. Müller's experiment, dating from 1838. This consists of the deepest possible expiration with the glottis closed, followed by a great inspiratory effort. The procedure as applied to hemostasis is recommended by G. Krebs (1903) who gives the instruction to inspire deeply with the mouth closed and to expire gently with it open. This may lead to syncope from a lowering of the cerebral blood pressure, and Sir Dundas-Grant believes it is the predominant factor in the production of what was formerly called "laryngeal vertigo," an error corrected by Peter Mc-Bride, who pointed out that it was really a "laryngeal syncope." Care should be exercised not to advise the practice of nasal inspiration when the nose is obstructed. The result of abuse of nasal inspiration is illustrated by the case of a middle-aged man who showed signs of dilatation of the heart. He stated that in order to keep up his muscularity he indulged in exercises which required forcible inhalation through the nose. Examination showed that both nasal cavities were almost completely occluded by the inferior tur-binated bodies. The restoration of free nasal breathing was followed by relief of the heart symptoms.—British Medical Journal, February 4, 1933, i, 3761.

Acne Vulgaris, a Symptom, Not a Disease.

—P. B. Mumford states that a number of very different etiological factors for acne vulgaris are cited in the literature. The commoner causes

would appear to be certain changes at pubertyparticularly menstrual disorders, seborrhea, constipation, incorrect diet, unhygienic physical life, and lack of local cleanliness. A careful study of 100 cases yielded the following findings: Fiftyfive per cent of the patients examined showed a general increase of sebaceous activity on the face, chest, back and scalp apart from any true comedones or pustules. Constipation of a degree sufficient to demand the regular taking of aperients was complained of in 60 per cent. Follicular perniosis was found on the palmar arcas and posterior upper arms. Peripheral cyanosis of greater or less degree was found in 28 per cent of the cases. A marked clamminess of the hands was found in about one-third of the cases. A palpable moisture on the hands, however, does not necessarily imply any increased secretion of moisture; it may be merely the result of a lowered peripheral temperature and consequent lessened evaporation. Peripheral temperature was raised very rarely indeed. In 40 per cent of the cases the amount of clothing appeared excessive, and many patients stated that they had always had a poor circulation. In 52 per cent of the cases more than six teeth showed decay, but the author is unable to find whether this is high for the average age of 21 years. Menstrual irregularity-variations of five days or more-was complained of as occurring at the onset of acne in 40 per cent of the cases. This variation was more commonly found in brunettes than in blondes. Acne appeared to have a later onset in brunettes than in blondes, but this may be due to the fact that comedones and excessive grease formation are less likely to be regarded as pathological in those of dark complexion. Mumford does not attempt an explanation of these findings, but thinks it is clear that acne cannot be regarded as a local disease of the skin with a single etiological factor. It is an expression of malfunction elsewhere in a certain group of susceptible individuals.—British Medical Journal, January 28, 1933, i, 3760.

A Simple Method for Accomplishing a Conservative Disinvagination in Intestinal Intussusception.—In operations on the intestine of the dog, says E. v. Redwitz, writing in the Deutsche medizinische Wochenschrift of January 13, 1933, such strong contractions of the intestinal tube are sometimes observed as to reduce it to the consistency of a hard cartilaginous cord. In order to make suture possible, the author's master, Enderlen, has often in such cases succeeded in relaxing the spasms by brushing the intestine lightly with tinctura opii simplex. It was astonishing to

see how the intussuscepting portion of the gut re fixed and how easily the intussuscepted portion could be freed frum its grasp, in some instances without the intervention of my kind of mechanical action. Redwitz has used the method in his own human cases, applying the medicament by means of a small swab. The first thing observed was a strong contraction, followed at once by a far-reaching relaxation of the wall of the gut, so that disinvagination took place either of itself or upon very slight pressure from below Caution is necessary, however, in the use of the procedure First, one must make sure that the tincture of opium is sterile, by keeping always at hand in the operating room a bottle whose contents have been tested and found sterile. In small children one must also be on guard against overdosage, since the sensitivity of these to laudanum is well known The opium is very rapidly resorbed by the serosa, and therefore produces its effect quickly Experience has shown that the best swab is one weighing 0.05 gm, which after saturation with fincture of opium contains 0012 gm thereof Estimating that only a small part of the opium applied will adhere to the gut, it appears that hardly more than 0006-001 gm opium will be effective, so that the danger of overdosage seems slight essential feature of the entire procedure lies in the fact that the spasmodic condition of the intussuscepting muscle can be relieved by application of antispasmodie drugs in minute quantities, and disinvagination thus accomplished without injury to the gut Naturally, the gut must be examined carefully with reference to its viability

Menstrual Changes in Intestinal Motility -Gustav Halter and Rudolf Pape say that the in fluence of the menstrual cycle upon the function of the digestive organs has hitherto been less clear than that of the genital cycle, and that statements about it in the literature have been contradictory Thus certain authors have spoken of menstrual hypomotility of the stomach while others have claimed to observe an opposite tendency authors have collected from a large number of patients an exact personal history in this regard and have at the same time carried out roentgen examinations of the menstrual and intermenstrual motility of the intestine in a series of cases. Of 481 women with a normal genital cycle only 12 per cent reported a tendency to constipation, and 91 per cent a tendency to diarrhea, at the time of menstruction But in 191 cases of chronic constipation 198 per cent reported normal action at this period. Thus it is seen that while only a small proportion of women with regular intestinal activity note a change in intestinal function, one fifth of all the women with habitual constipation observe a normal state of elimination at the time of menstruation Roentgen examinations were car ried out in 15 cases during the first three days of

the period, and were controlled twice daily by full evacuation of the barmin. In eight cases, that is more than half, an increase of intestinal motility was demnistrated but in only one case did this exceed the normal degree,—a circumstance which inay explain the difference between the respective results of the subjectively and the objectively conducted examinations. In five cases there was no change, and in two there was a decrease of intestinal activity. In four of five cases which exhibited habitual constipation between periods, the intestinal function was normal during the periods; in one case its activity was increased. The mechanism of the increased motility differed considerably in individual cases. Thus in some cases, along with an acceleration of transportation there was a decreased tonus of the circular musculature, in others, there was an increase of tonus, or normal transportation, but increased urge to defecation These phenomena might be due to the increased influence of several hormones upon the intestine. Against this stands the fact that men strual increase of motility was observable only in a small number of those cases which were habitunlly regular Probably several eauses combined to produce the results. It is possible that the es sential factor in these observations consists in an improved correlation of the different processes concerned in intestinal movement, which are dis sociated in habitual constipation. This reflex association is promoted by the menstrual increase of irritability of the entire autonomic nervous six If, conversely, the threshold of irritability rises during the intermenstruum, the various pathologic forms of intestinal activity return -Deutsche medizinische Wochenschrift, February 10 1933

The Effect of Tonsillectomy on the Occur-rence and Course of Acute Polyarthritis -Maxwell Finland, William B Robey and Harry Heinmann present an analysis of the records of 654 consecutive cases of acute migratory polyarthritis for the purpose of determining whether or not tonsillectomy had altered the course of the attack or had affected the frequency of recurrence Of the 654 patients 335 were admitted for an in itial atack, and the remaining 319 were admitted for recurrences Of the 335 admitted for an initial attack 42 or 13 per cent, had previously had a tonsillectomy, whereas 72, or 23 per cent of the 319 admitted for recurrences previously had had tonsillectomy Thus twice the percentage of cases previously subjected to operation were admitted for a recurrence as were admitted for an initial attack The proportion was quite simi hr m each of the age groups Rheumatic heart disease was about twice as frequent in the group of patients admitted for recurrent attacks as among those admitted for an initial attack seems that previous tonsillectomy had no striking

effect in reducing the incidence of cardiac lesions in this series of cases. The cases previously subjected to tonsillectomy were quite comparable with those having no operation with respect to the total duration of the joint symptoms. The tabulated figures show that with respect to the duration of fever in the hospital there was very little difference between those patients having had no tonsillectomy, those subjected to this operation before entry, and those operated upon in the hospital. With reference to the duration of hospitalization, the patients who had had no tonsillectomy had, on the whole, the shortest stay in the hospital, and those subjected to tonsillectomy before entry had a somewhat longer period, but not so long as those who were operated upon during their stay. Approximately one-half of the patients who were operated upon while apparently quiescent showed evidence of activity following the operation, but in only six were there serious The average number of recurcomplications. rences in the patients admitted following tonsillectomy was about the same as in those not previously operated upon. The attacks, however, were much closer together in the cases previously tonsillectomized. The authors suggest that in private practice where patients can be studied with greater care and an operator of experience can be selected, the results are often far more satisfactory.—The American Heart Journal, February, 1933, vii, 3.

The Initial Symptoms of Acute Articular Rheumatism and Their Pathogenetic Significance.—According to Gustav Singer, acute articular rheumatism, or rather, the nucleus of this complex, acute infectious arthritis, exhibits. as do most infectious diseases, certain prodromal manifestations of a regular character. In the forefront of these stand affections of the throat and pharynx, which are regarded as the commonest portal of entry of the exciting agent of the disease. The overwhelming predominance of the streptococcus as the exciter of important anginas served as a strong support clinically for upholding the etiologic significance of this microorganism for infectious arthritis. Since this concept gained ground, other streptococcus affections have been recognized as forerunners of rheumatism, among them sinus affections, certain forms of otitis. alveolar pyorrhea and peridental foci of infection. While these are the most frequent states leading up to rheumatism, it happens not infrequently that a longer or shorter time before the outbreak of the joint symptoms, there is a general feverish condition, which sets in either suddenly with a chill, or slowly with tumor of the spleen and diarrhea, presenting a clinical picture which resembles that of typhoid. The transient joint eruption is well known to be a frequent phenomenon, but one that does not constitute an essential part of the di

picture. In the hyperpyretic form of rheumatism there are often severe general nervous symptoms (cerebral rheumatism), which must be regarded as the result of toxic changes. The not unusual combination of acute rheumatism with chorea. which may precede the process, must be considered the sign of a pyogenic infection. The purpura, peliosis and erythema multiforme are regular symptoms of definite bacterial invasions. which have also been demonstrated in embolic form in the skin. But the most fundamental and characteristic mark of the infectious nature of acute rheumatic infections is the localization of the manifestations in the heart, as endocarditis, pericarditis, pancarditis, which are present in over 80 per cent of cases. Frequently the subendocardial nodules described by Aschoff-Tawara, resembling giant cell complexes, have been found existing for years as the seat of the rheumatic in-Of special significance is the development of typical Aschoff's nodules in arterio- and arteriolo-sclerosis, and in periarteritis nodosa. A complete study of the subject teaches that the invasion of this stubborn infection occurs through the blood stream, from which all the clinical manifestations develop. One should never forget that it is through the blood that the rheumatic affection is carried to the most important organ, namely the heart. As Lasègue has so aptly put it: "Acute rheumatism licks the joints, the pleura, even the meninges, but it bites the heart." Münchener medizinische Wochenschrift, December 16, 1932.

Paradoxical Breathing.—Ephriam Korol defines paradoxical breathing as the deflation of the lung or a portion of the lung during the phase of inspiration and the inflation of the lung during the phase of expiration. This type of breathing occurs in all air-breathing vertebrates. It depends on the same anatomical factors as the residual air and seems to serve the same purpose. It is caused by narrowing or closing of the glottis during certain respiratory acts and on the unequal pressure conditions in the different portions of the respiratory tract. In the amphibians and birds, paradoxical breathing, like the maintenance of residual air, serves a useful function in moistening and diluting the atmospheric air. In mammals, owing to the oxygenation of the blood in all portions of the lungs, paradoxical breathing impairs the respiratory function by diminishing the vital capacity and by causing breathing of stale air. With an intact thoracic wall, the paradoxical breathing is limited to the apical and mediastinal portions of the lungs, these regions of the chest being poorly provided with muscle. In congenital and acquired defects of the chest wall, the vicarious breathing is conspicuous in the areas of the lungs adjacent to the defects. During the activities of workers such as glass blowers, singers, dancers, and runners, the paradoxical breathing produces acute emphysema and materially curtails

the efficiency of the performers. This type of breathing is an important factor in the development of pulmonary edema and is largely responsible for the dyspnea and cyanosis observed in emphysema and asthma. Paradoxical breathing has been described repeatedly in open pneumothorax, both in the human subject and in the experimental animal. It occurs in hernia of the lung, in tuberculosis and other pulmonary infections, and after extensive operations on the wall of the chest. The prognosis in tuberculosis and bronchiectasis is better for persons of sedentary occupation, for the reason that these persons do not engage in strenuous muscular effort, with the concomitant paradoxical breathing. By causing an interchange of material between the lungs, paradoxical breathing is a common cause of the interbronchial spread of infection in tuberculosis and all other diseases of the lungs,-Archives of Internal Medicine, February, 1933, li, 2.

The Significance of the Porphyrins in the Pathology of Digestion.-Under physiologic conditions, says I. Boas, in the Deutsche medizinische Wochenschrift of January 27, 1933, small amounts of porphyrin are found in the blood, gallbladder, meconium, urine and feces. author's investigations were concerned with the behavior of the stercoporphyrins in ulcers and tumors of the intestinal tract. Here 3 kinds of porphyrin are especially to be differentiated: (1) koproporphyrin, (2) protoporphyrin and (3) deuteroporphyrin. Physiologically, and even in hemorrhage, koproporphyrin appears only in very small traces in the intestinal canal. If there is more than a trace, its differentiation from the other 2 porphyrins is urgently necessary for avoidance of error. Between the 2 latter, fundamental differences exist. Protoporphyrin is found in the stools of both healthy and sick individuals, especially in gastric ulcer; Boas regards it as impossible to distinguish physiological from pathological, that is hematogenous, protoporphyrin. With deuteroporphyrin, however, the case is different. These substances are not met under normal conditions. Every possible precaution must be taken with reference to the demonstration of occult bleeding. If this is done, the demonstration of the presence of denteroporphyrin has a clinical diagnostic significance, as follows: (1) In ulcers with positive blood reactions, it is not the disappearance of these but that of deuteroporphyrin which shows that the ulcer has reached the stage of cicatrization, or nearly so. (2) In ulcers with negative blood reaction and with unequivocal findings roentgenologically and clinically, the repeated demonstration of deuteroporphyrin shows that a peptic defect has not yet cicatrized. (3) A persistent negative deuteroporphyrin finding (with negative blood reactions) shows, despite a reliable Roentgen picture and

elinical symptoms resembling ulcer, that a cicatrized ulcer must be assumed, possibly along with chronic gastritis. (4) From the standpoint of therapy, it is important that an ulcer shall not be regarded as cured until examinations for deuteroporphyrin give repeated negative results. Of even greater importance than examinations for stereoporphyrin are those for uroporphyrin. All urine with exerction of bile pigments is strongly suspicious of increased porphyrinuria. Boas has observed porphyrinuria in diseases of the liver and gallbladder, when in a stage of acute inflammation. He has seen it appearing periodically at the close of a severe hematemesis or melena. In internal bleeding, its presence may be an important sign that bleeding has been renewed. A careful distinction should be made between periodic and chronic porphyrinuria. A striking chronic porphyrinuria has been observed in metastatic careinoma of the liver, where the primary growth was in the stomach or colon. Up to the present time no simple and exact method of quantitative determination of either stercoporphyrin or uroporphyrin, suitable for clinical use, has been devised.

Intestinal Obstruction Caused by Food .-- In a search of the literature on intestinal obstruction caused by food Elliott (1932) found 39 cases of this type since 1910, to which he added a case in which the obstruction was caused by orange pulp. Frank B. Block, writing in the American Journal of the Medical Sciences, March, 1933, clxxxv, 3, reports a similar case due to the same cause. The patient, a woman aged 57 years, was admitted to the hospital with the diagnosis of intestinal obstruction of undetermined origin, although on account of her age a carcinoma of the bowel was suspected. At operation the lower ileum was found to contain a mass between two and three inches long which felt boggy and completely obstructed the bowel at this point. As the mass was within the lumen of the bowel, an enterostomy was performed. Examination of the specimen removed showed that it was composed of two sections of orange which had become impacted side by side. Positive identification was made by the finding of a few orange seeds inside the mass, and the patient stated that she had eaten oranges about twelve hours before the onset of pain. Because she had no teeth she swallowed the orange without eareful mastication. After operation all of the abdominal symptoms subsided very promptly, but a bilateral pneumonia developed from which she died ten days later. This case presents most of the features which Elliott found in his review, such as an edentulous patient, short interval between the ingestion of the orange and the onset of obstruction, the site of the obstruction in the lower ileum, failure of accurate diagnosis of the eause of the obstruction, and a fatal termination.

THE MEDICAL GRIEVANCE COMMITTEE DECIDES AN IMPORTANT CASE

By Lorenz J. Brosnan, Esq.

Counsel, Medical Society of the State of New York,

The public generally, we believe, is not aware of the splendid work done by the members of the Medical Grievance Committee of the State Department of Education. This Committee, under the able leadership of its Chairman, Dr. Orrin Sage Wightman, has rendered distinguished service not only to the medical profession, but to every citizen of the State.

The attention of the public has been focused upon this Committee by reason of a recent case before it which was reported in the public prints and commented upon editorially by some of the leading newspapers in the State. Dr. Wightman feels, and your Counsel agrees with him, that by virtue of the importance of the questions involved, this case should be called to the attention of the members of your Society through the medium of this column. The facts, briefly, are these:

Last summer proceedings were started under Section 1265 of the Education Law, by the Executive Director of the City Affairs Committee of New York against five duly licensed physicians for the purpose of revoking their licenses. The petitioner charged these physicians with fraud and deceit in the practice of medicine which, under Section 1264 of the Education Law, is one of the grounds for disciplinary action. The charges were that four of the doctors had been appointed by the Corporation Counsel of the City of New York to handle the treatment of compensation cases, and that each of the said four doctors had split their fees with the fifth, Dr. Walker, the brother of ex-Mayor Walker. It was further charged that the splitting of fees with a doctor who had rendered no service to the City in return therefor, was prima facie evidence that the motive was to obtain political influence. There were also charges that the four doctors had received excessive compensation for the services that they actually rendered and that their bills had been padded.

A preliminary hearing was held and evidence was submitted by the petitioner in support of the charges. After deliberation, the Committee on Grievances determined to hold a formal trial to hear the evidence and to pass upon the guilt of the doctors, who were referred to in the proceedings as the respondents. A sub-committee was appointed for that purpose. The respondents appeared in person and by counsel. A number of hearings were held and after the petitioner had

submitted his case, counsel on behalf of the physicians-respondents moved to dismiss the charges on the ground that no proof had been adduced before the sub-committee sufficient to sustain the charges made. These motions were taken under advisement by the sub-committee, and after due deliberation it reported to the Grievance Committee and recommended to it that, upon the record before the sub-committee, the charges should be dismissed and the respondents exonerated from the charge of fraud and deceit in the practice of medicine. The report and recommendations of the sub-committee were unanimously adopted by the Grievance Committee.

In its report the sub-committee, although it found that the charges should be dismissed, voiced its disapproval of the manner in which the City had been accustomed to handle the medical treatment of compensation cases. The report stated in this regard in part as follows:

"Before proceeding with our consideration of the charges themselves, we feel it our duty to comment on the system adopted by the City in these matters, for same is repugnant to good government and leads to manifest abuses. We deplore the method pursued in the selection of the designated physicians as disclosed here. Though there was some testimony as to qualifications taken into consideration by Mr. Strauss when the physicians were designated or continued, we believe that their qualifications were subordinated to political favoritism. The record is devoid of any semblance of a careful investigation into the ability and standing of these physicians, nor did it appear that any recommendation had been sought by the Corporation Counsel of any recognized medical body. We do not intend by this to cast any reflection upon the ability of respondents, but criticize the method of their selection. We believe that in matters of a public nature, when it is sought by a municipality to engage physicians who are to be paid out of the taxpayers' money, that such physicians should be selected either from a competitive Civil Service list or from a list furnished by a board of physicians of conspicuous standing, or through other channels of organized medicine.

"It also appeared before us that in cases in which the injured were treated by their family physicians or in hospitals, they were frequently turned over to the designated physicians for medical attention. This was sought to be justified either because of objections of those connected with the city's compensation bureau, or because of demands made by labor organizations for private treatment of their members who were in hospitals. We are not satisfied with the explanation. Unless the City's interests otherwise require, we believe that when an injured employee is receiving proper medical attention by a physician of his own selection or at a hospital, there should be no substitution of another physician.

"Except for a casual statement that when a bill was thought to be unreasonable, it was referred to the Labor

Department, there was no proof of any system whereby the reasonableness of the bills was passed upon. Even as to the casual statement to which we have referred, there was no proof as to how it was deemed unreasonable, nor was there a single case indicated in which that had been done. It was conceded that the check-up consisted merely of the calculations, that is, whether the totals were correct, for the bureau had no facilities to check same otherwise. The employees were permitted to visit the physician ad libitum without any supervision whatsoever. At times they were told to return to the bureau after a specified period had clapsed, but no record was kept as to when they were to return or whether they did return. This loose manner of spending City money is appalling. Ordinary business methods require the maintenance of records by which the interests of the City are guarded. A single procedure would be to have all bills accompanied by a sworn statement setting forth the name of the injured, where employed, date of accident, nature of injury, dates and nature of treatments and fees therefor."

In considering the evidence of fce-splitting between the various doctors and Dr. Walker, the report of the committee was to the effect that under the law and the decided authorities proof of fee-splitting would not in and of itself constitute fraud or deceit in the practice of medicine. The sub-committee found that the Legislature in enacting the Medical Practice Act had not intended to provide for discipline on charges of unprofessional or unethical conduct or fee-splitting. As the report said:

"We have ruled that fee-splitting her se does not constitute fraud or deceit in the practice of medicine for the fact that one physician has paid to another physician a part of a fee does not necessarily prove any fraudulent act on the part of either one of them. We must construe the words, 'fraud or deceit' in their ordinary meaning, guided by the provision of the staunte that our findings must be based on 'sufficient legal evidence.' Fraud and deceit in the practice of medicine cannot be spelled out from the acts of those of the respondents who paid and received the moneys under consideration, for, as we will later point out, no fraudulent or deceitful act or deed was established."

However, although it ruled that fee-splitting did not justify action on the part of the Grievance Committee, the report made clear its opinion of the practice as follows:

"We do not intend to hold that fee-splitting in any case, even though frand and deceit are absent, is pro-

fessional. Quite the contrary, we frown upon such practices and condemn sanc as being obnoxious and against the best interests of the community, in view of the gravabuses which result therefrom. Nevertheless, we cannot lay down a general rule in this statutory proceeding that fee-splitting fer se constitutes fraud or deceit despite the absence of any act constituting fraud or deceit. That would be presuming fraud which we may not do. We may not guess or conjecture but rather must have definite evidence from a legal standpoint, showing wilful fraud committed for the purpose of deception."

In connection with the charge that the physicians involved had padded their bills, the subcommittee held that no proof had been adduced by the petitioner sufficient to sustain this charge. On this point the sub-committee said:

"Without any proof that the treatments were innecessary, we cannot hold that the physicians' bills were padded. It would be indulging in speculation if from the fact that the treatments and visits were numerous, we should infer that they were not wholly necessary. This Committee might suspect that in one case or another the length of treatment was not commensurate with the severity of the injury; but on what could we base the further inference that those of the doctors here on trial, who had first-hand knowledge of the condition of the injured as shown by the reports, who examined the employees, who diagnosed their conditions, and who treated them, knew that the treatments were nunceessary, and that by their hills they intended to defraud the City? To draw that inference would be unreasonable, and would be basing an inference on an inference, which would be unjust and improper. To bring an inference mithin the 'sufficient legal evidence' rule, the inference must be based on fact. Furthermore, as indicative of treatments, but the Labor Department directed that they continue.

"The amounts paid by the City for medical expense in the treatment of injured City employees do not indicate any fraudulent acts."

The sub-committee concluded its report with the following recommendation:

"We also recommend that Section 1264 of the Educational Law be amended so as to include unprofessional and dishonorable conduct as ground for disciplinary proceedings against physicians."

We trust that this amendment will find favor with the Legislature. It is a most salutary and necessary recommendation and one that should be adopted without delay.

BROKEN NEEDLE EMBEDDED IN JAW

A middle-aged woman was being given local anesthesia for the purpose of extracting a tooth when the needle broke. The dentist sent her to a hospital and recommended that a certain surgeon be called into the case to attempt to remove the needle. The said doctor caused an x-ray picture to be taken which showed that a piece of the needle, about one-half inch long, was lodged in the patient's mandible, lying parallel with the

bone and in the periosteum. Under a general anesthesia the doctor made an incision over the region where the needle was located. He exposed the bone but could not observe the needle. After attempting to find the needle by probing and failing to locate the same he concluded that the needle had been pushed into the foramen of the bone and that it was causing no annoyance or harm. He believed that it would be necessary

to chisel into the bone to remove it and decided against such procedure for fear that a condition of osteomyelitis might develop. He then sutured the incision and turned the case over to another doctor.

Subsequently an action was commenced against the surgeon, charging him with malpractice in failing in his attempt to remove a portion of the needle from the plaintiff's jaw. The complaint charged that as a result of the defendant's negligence the plaintiff suffered a paralysis of the muscles of her mouth and jaw and that she had sustained repeated abscesses, swellings, infection of the mouth and jaw, and that she had been unable to eat normally since the performance of the operation.

The answer interposed on behalf of the defendant denied all allegations of negligence contained in the complaint. The case was never noticed for trial on behalf of the plaintiff. After considerable time had elapsed and no steps had been taken by the plaintiff to bring the matter on for trial, a motion was made to dismiss the summons and complaint for lack of prosecution. Said motion was granted, terminating the matter in favor of the doctor.

ERRONEOUS DIAGNOSIS OF TUMOR

A general practitioner referred to a physician who specialized in general surgery, a woman about 42 years of age, for examination, diagnosis and operation, if necessary. The tentative diagnosis which had been made by the general practitioner was that of abdominal tumor. The surgeon five years previously had performed an operation upon the patient for the removal of gall stones. At the time of that operation he had detected the presence of an ovarian cyst about the size of a lemon. At that time the cyst seemed to be causing no particular harm to the patient and as it was in a different field from that involving the gall stone operation, he did not undertake to remove the cyst.

The surgeon examined the patient and took her She had been married about twentyfive years and had never been pregnant. menstrual history was very much confused. For long periods of time she had not menstruated although she had never been pregnant. At the time of the examination the surgeon was informed that she had not menstruated for some months. His examination showed the presence of a mass which was not quite located in the center of the abdomen. In view of the various circumstances the surgeon concluded that the woman was not pregnant but that her old ovarian cyst had suddenly enlarged and was now causing her trouble. No x-ray was taken to confirm the diagnosis. The question of pregnancy was considered but was ruled out in the light of all the circumstances. Operation was suggested and a day later the patient entered the hospital and the doctor operated upon her. Upon opening the abdomen he immediately detected the pregnancy about the size of a grapefruit which was probably in about the The doctor observed certain adfifth month. hesions in the region of the gall bladder and the left ovary and after liberating the said adhesions he closed the wound without further operation. He did not do anything which in any way interrupted the pregnancy. After the operation the doctor frankly told the husband of the patient that his diagnosis had been erroneous and that the patient was pregnant and that in all probability in due course she would give birth to a child. The patient recovered from the effects of the operation very satisfactorily and left the hospital in good condition, returning to the care of the general practitioner who had referred the case for examination and operation.

About four months after the operation the woman was delivered of a normal living child by cesarian section. According to the doctor who performed the cesarian operation the reason for delivery by that method was that the age of the patient indicated such procedure.

Some time later an action was started against the surgeon who had operated upon the patient for a supposed tumor, charging him with malpractice. The case came on for trial and the plaintiff attempted to charge the surgeon with negligence in the diagnosis which he had made. It should be noted that during the trial the woman, a robust person, sat in the courtroom with her baby, an obviously strong healthy in-The plaintiff's attorney atfant, in her arms. tempted to adduce evidence to the effect that x-rays should have been taken but no doctor testified that it was customary procedure for x-rays to be used under the circumstances. A further attempt was made to bring out testimony to the effect that the Asheim-Zondek test for pregnancy should have been used, but the testimony clearly showed that the said test was not in use in the community at the time that the examination was made.

The case was submitted to the jury and a verdict was rendered in favor of the doctor of no cause of action, thereby exonerating him of all charges of malpractice.

HOUSE OF DELEGATES

MINUTES OF THE ANNUAL MEETING, APRIL 3 AND 4, 1933

The 127th Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Waldorf-Astoria, New York City, New York, on Monday, April 3, 1933, at 2 P. M.

Dr. George W. Cottis, Vice-Speaker; Dr. Daniel S. Dougherty, Secretary.

The Vice-Speaker: The House of Delegates will please come to order.

1. COMMITTEE ON CREDENTIALS

The Vice-Speaker: The first order of business is the

report of the Committee on Credentials.

The Secretary: The Committee on Credentials finds no disputed delegations and all those whose names are

on our roll are entitled to vote.

The Vice-Speaker: The next order of business is calling the roll.

The Secretary called the roll by counties.

The Vice-Speaker: A quorum being present, we will proceed with the business of the House.

2. APPROVAL OF THE MINUTES

The Vice-Speaker: The first order of business is the reading of the minutes of the previous meeting.

The Secretary: As these minutes have been published, I move that the reading be dispensed with and that they be adopted as published in the June 15th, 1932 issue of the New York State Journal of Medicine, page 732.

Motion seconded and carried.

3. Reference Committees

The Secretary: Mr. Speaker, I move that the President's report and the reports of all the Officers and Conmittees, having been printed and sent to the Delegates, be referred to the respective Reference Committees without further reading.

Motion seconded and carried.

The Vice-Speaker: I will ask the Secretary to read the list of Reference Committees.

The Secretary read the following Reference Com-

REFERENCE COMMITTEE ON REPORT OF THE PRESIDENT:

Luther F. Warren, Chairman, Kings Louis A. Friedman, Bronx William P. Howard, Albany George M. Fisher, Oneida Herbert A. Smith, Eric

REFERENCE COMMITTEE ON REPORT OF SECRETARY. COUNCIL AND COUNCILORS:

Harrison Betts, Chairman, Westchester Walter T. Dannreuther, New York William A. Krieger, Dutchess-Putnam Albert L. Voltz, Queens, Albert G. Swift, Onondaga

REPERENCE COMMITTEE ON REPORT OF TREASURER AND TRUSTEES:

Edward R. Cunniffe, Chairman, Bronx John J. Masterson, Kings Franklin Walker, New York William T. Shauahan, Livingston W. Grant Cooper, St. Lawrence

REFERENCI: COMMITTEE ON REPORT OF LEGAL COUNSEL:

Augustus J. Hambrook, Chairman, Rensselaer Charles C. Trembley, Franklin Edward C. Podvin, Bronx Carl Boettiger, Queens Willard H. Veeder, Monroe

REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON PUBLIC RELATIONS:

Reeve B. Howland, Chairman, Cheming John J. Buettner, Ouondaga Arthur F. Heyl, Westchester Leon M. Kysor, Steuben Luther C. Payne, Sullivan

REPERENCE COMMITTEE ON REPORT OF COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION:

George S. Towne, Chairman, Saratoga Thomas M. Breman, Kings Edgar A. Vander Veer, Albany Richard H. Sherwood, Niagara Herbert B. Smith, Steuben

CREDENTIALS:

D. S. Dougherty Peter Irving

4. REPORT OF SPECIAL COMMITTEE ON THE COSTS OF MEDICAL CARE

Dr. Kopetzky: Mr. Speaker, I move that this House establish a special order of business this evening and that the first order of business after we re-convene from our dinner shall be the consideration of report of the Special Committee on the Report of the Committee on the Costs of Medical Care and that there be allowed at least one hour for its consideration.

Motion seconded and unanimously carried.

5. New Business

The Vice-Speaker: We will now proceed to new business. Is there anything to come up before the House under new business?

6. RACIAL DISCRIMINATION

Dr. Colie of New York presented the following reso-

The Medical Society of the State of New York believes that there should not be nationality in science or medical progress and it views with concern any policies at any time or in any place that tend to discriminate between professional men in terms of race or creed.

The Vice-Speaker: This resolution will be referred

to Reference Committee on New Business A. (Rep.

Sec. 50.)

7. Nurse Anesthetist

Dr. Kaliski of New York, presented the following resolution:

Whereas, at the time of the passage of the Medical Practice Act, and for many years thereafter, it was the accepted interpretation that the administering of an anesthetic by any one except a licensed physician or dentist was illegal, and this also was evidenced by the ban on the administering of anesthetics by duly licensed osteopaths;

Whereas, during the past ten years or so there has been an insidious usurping of the duties and rights of duly licensed physicians by lay technicians and nurses who administer anesthesia despite the fact that there has been no change in the Medical Practice Act; and

Whereas, during this same period there have been marked advances in the physiological, chemical, mechanical, and therapeutic problems involved in anesthesia to none of which non-medical technicians have made any

contribution; and Whereas, these advances have reached a stage where they require a medical education for their proper inter-

pretation and safe utilization; and

WHEREAS, the present custom in many hospitals of having non-medical technicians administer anesthetics deprives the residents or internes of opportunities for instruction in this important branch of medicine, yet these same doctors, untrained in anesthesia, will subsequently be the ones the law assumes to be qualified to give, supervise, and to accept full responsibility for the administration of the anesthesia; and

VHEREAS, the inroads of these technicians have tended to discourage medical graduates from entering this field of medicine, and have decreased the likelihood of qualified medical successors to those who have been so instrumental in advancing the art and science of anesthesia; and

WHEREAS, the giving of an anesthetic involves on the part of the operator the exercise of judgment, discretion and skill, and is not merely a mechanical performance which can be routinely performed by any untrained individual without jeopardy to the patient; and

Whereas, the successful administration of anesthesia requires the exercise of proper medical care during the procedure, involves an examination of a patient to determine his physical ability to undergo the process and a careful watching of the patient during the administration of the anesthesia to determine its effects and the quantity administered; and

WHEREAS, the prevalent custom of evasion of the spirit of the law by the technical assumption of responsibility by the operating surgeon is a mere subterfuge, as the surgeon in most hospitals rarely selects or inquires into the technician's qualifications, does not usually supervise the administration of the anesthetic at its most critical period, namely the induction, and even though present during its maintenance the surgeon, because of his interest in the operative procedure, cannot always promptly detect the necessity for therapeutic intervention, which determination must be left to the judgment of the anesthet-

WHEREAS, many hospitals and private sanitaria advertise to the public and the profession that an anesthetist will be available; this being a misrepresentation when such anesthetist is only a technician, while the general assumption is that the term anesthetist implies a physi-

cian; and

WHEREAS, since the surgeon is by law responsible for the act of an agent, if in fact the lay anesthetist is the doctor's agent when administering an anesthetic, the surgeon assumes a responsibility and liability which under certain circumstances may nullify the effect of his malpractice coverage if it can be proved that such lay anesthetist is performing an unlawful or illegal act; and

WHEREAS, our acquiesence to the encroachment by nonmedical technicians in the field of anesthesia, on the prerogatives of the physician, will make it increasingly difficult to exclude the osteopaths and others from these same privileges, for if any division of medicine desires to nullify any section of the Medical Practice Act it can do so by the subterfuge of assuming the responsibility, then other divisions of medicine must, in justice, be accorded the same privilege and the whole Act be thus THEREFORE BE IT weakened.

RESOLVED: That the Medical Society of the State of New York affirm that the giving of an anesthetic constitutes the practice of medicine and insists on the strict observance of the provisions of the Medical Practice Act, without subterfuge or evasion; and BE IT FURTHER RE-

That if it is the opinion of the Attorney-General that non-medical technicians practicing anesthesia are not violating the law under present conditions, that the proper procedure be instituted to obtain legislation which will include anesthesia in the practice of medicine or limit the administration of anesthesia to duly licensed dentists or physicians.

Referred to Reference Committee on New Business C.

(Action, Section 39.)

8. FEE-SPLITTING

Dr. Kaliski of New York, presented the following resolution:

During the year 1932 the Committee on Civic Policy of the Medical Society of the County of New York made an exhaustive study of the problem of the secret division of fees, popularly known as secret fee-splitting. It held a number of open meetings at which many prominent physicians and surgeons as well as others interested in the practice of medicine from the hospital and administrative standpoint, submitted their opinions on this

At least four open meetings were devoted to the taking of testimony, while at other meetings the Committee

itself wrestled with this difficult problem.

As a result of their deliberations, the Committee on Civic Policy came to the conclusion that the essential cause of fee-splitting was in all probability economie They felt that the great majority of young medical men began practice with the highest professional ideals, but for one reason or another, many of these younger men, particularly in the larger cities, began the practice of the secret division of fees. The ethical family praetitioner is often so poorly paid in comparison with the surgeon or specialist, particularly in normal times, as to

make it difficult for him to earn a decent living. The Committee recognized fully the evils of sceret fecsplitting, the corrupting influence on the practitioner, and the specialist, the possibility of betrayal of a patient through reference to an interior surgeon or specialist because of his willingness to indulge in the practice of secret fee-splitting. The influence of secret fee-splitting on the younger surgeon and specialist in building up a specialty practice was particularly noted. results of secret fee-splitting on the public because of the referring of the public to men of lesser ability due to their willingness to split fees is an Important factor in the consideration of this problem. The Committee was unanimous in condemning all forms of secret fce-splitting, commissions and rebates.

In order to cope with the existing evil and, if possible, to lesson or control it, the Committee made the following recommendations to the Comitia Minora of the Medical Society of the County of New York, which were accepted by it and finally adopted by the Society at a

stated meeting:

"I. The Comitia Minora condemns the practice of the secret division of fees in the strongest possible terms.

"2. The Comitia Minora calls upon consulting specialists and surgeons to join with the County Society in the education of the public by explaining to patients and their families the nature and value of the family physician's services before, during and after operation, and the

necessity for his proper compensation.

"3. Where essential pre-operative and post-operative service is rendered by the family physician in a surgical case, an adequate fee should be paid to him for his service. In the opinion of the Comitia, it is desirable that the family physician's bill for this service be rendered at the same time as the bill of the surgeon, in order to establish in the patient's mind the essential importance of both services.

"4. A joint bill may be rendered to a patient for the combined services of physicians and surgeons participating in the conduct of a case, and shall specify the sum

allocated to each total amount. "The Comitia uny joint bill which does not to each par-

ticipant in a given case."

In view of the importance of the problem of secret feesplitting to the public and to the profession alike, we respectfully memorialize the Medical Society of the State of New York, in convention assembled, to endorse the recommendations proposed by the Medical Society of the County of New York, and we call upon the convention to suggest such steps as will lead to the adoption of these principles of professional conduct as an integral part of the Principles of Professional Conduct of the Medical Society of the State of New York.

The Vice-Speaker: Referred to Reference Committee

on New Business C. (Report in Section 38.)

9. Allocation of Money to District Branches

Dr. Allison of Nassau, presented the following resolution:

WHEREAS: Since, due to the present economic conditions, the several District Branches and their component County Societies have great difficulty in balancing their budgets, and in providing funds for such purposes as carrying on their rolls and otherwise assisting indigent members, previously in good standing; and in order to avoid the necessity of retrenchment of normal standard activities of the District Branches and County Societies therefore

BE IT RESOLVED: that the Executive Committee and the Board of Trustees be requested to allocate three dollars (\$3,00) per member back to the District Branches for such utilization as in their judgment may be wise.

The Vice-Speaker: This resolution will be referred

to Reference Committee on New Business B. (Action. Section 45.)

Is there any other new business?

10. Woman's Auxiliary

Dr. Menckeu of Queens, presented the following reso-

lution: Whereas, the American Medical Association at its meeting in St. Louis in 1922 endorsed the motion for the formation of a Woman's Auxiliary to the American

Medical Association, and

WHEREAS, in July, 1932 there were thirty-six State Auxiliaries and the District of Columbia Auxiliary in addition to a County Auxiliary in each of two States functioning as State Auxiliaries; and

WHEREAS, a Woman's Auxiliary to the Medical Society of the County of Onecus has been formed and is func-tioning, therefore, be it

RESOLVED, that it is the sense of this meeting that a Woman's Auxiliary to the Medical Society of the State of New York be formed and that the Woman's Auxiliary to the Medical Society of the County of Queens be endorsed and requested to function as the nucleus of the New York State Auxiliary, with five (5) members of the State Society to be appointed by the President and these five members shall act as a Council for the guidance of this Anxiliary.

The Vice-Speaker: This resolution will be referred to Reference Committee on New Business A. (Action, Section 51.)

Is there any other new business?

11. RADIOLOGICAL SECTION

Dr. Taylor of New York, presented the following resolution:

1. Whereas it would be to the benefit and best interests of the Medical Society of the State of New York, 2. Whereas it would be to the best interests of the NEW YORK STATE JOURNAL OF MEDICINE.

3. Whereas it would be for the good of the Medical

and Surgical Profession.

4. WHEREAS it would be savorable to the general education and mutual benefit of the roentgenologists of this Society and state.

5. Whereas this would reflect also to the advantage of

patients and the public generally.

6. WHEREAS the temporary session granted has proved

a definite success.

7. WHEREAS Roentgenology has become a very important integral part of our profession. And

8. WIERRAS the five individual X-ray societies, namely—The New York City, the Brooklyn, the Central New York, the Rochester and the Buffalo groups desire this

section. Therefore, be it asked and resolved that the House of Delegates of the Medical Society of the State of New

York establish a section known as the Radiological Section of the Medical Society of the State of New York.

The Vice-Speaker: This resolution will be referred to

Reference Committee on New Business B.

The Secretary: We have something similar here regarding the formation of a section on Physical Therapy, and also one on Urology. I should suggest that they all be placed together and referred to the same committee, if you would allow me to suggest it.

The Vice-Speaker: So ordered. These three recom-

mendations are all referred to Reference Committee on New Business B. (Action, Sections 46 and 47.)

Any further new business?

12. CERTIFICATION OF QUALIFIER SPECIALISTS (Sec also Section 15)

The Secretary: The Assistant Secretary will read the resolution presented by Dr. Walter T. Danureuther of New York County.

The Assistant Secretary read the following resolution:

Whereas, the American Board of Ophthalmie Examinations, the American Board of Oto-Laryngology, the American Board of Obstetrics and Gynecology and the American Board of Dermatology and Syphilology have been organized by their respective National Societies, together with the corresponding scientific Sections of the American Medical Association, have functioned suceessfully under the supervision of the parent bodies, and have been endowed with the prestige of the sponsoring societies, and

Whereas, at least two additional special groups are contemplating the creation of similar Boards in the near

future, and

Whereas, the efforts made by the existing Boards to certify well qualified specialists have met with the approval of the medical profession at large, and

Whereas, the personnel of such examining Boards is best selected by the sponsoring National Societies, and Whereas, the autonomy and independence of each of

the special Boards is essential to preclude political domin-

ation or control by extraneous influences,
THEREFORE, BE IT RESOLVED that the House of Delcgates of the Medical Society of the State of New York instruct its delegates to the American Medical Association, at the meeting in Milwaukee, in June, 1933, to further any and all Resolutions which have for their purpose the advancement of these well established efforts to certify well qualified specialists, and to oppose any and all Resolutions which have for their purpose interference with the constituted authority and activities of the Special Examining Boards as they now exist.

The Vice-Speaker: This resolution will be referred to Reference Committee on New Business C. (Action,

Section 41.)

13. Malpractice Defense and Group Insurance

The Secretary: I have a supplementary report on the Regulations Governing Malpraetice Defense and Group Insurance. These have been passed by the Executive Committee and are now submitted to the House for final action. I will ask Dr. Sondern, Chairman of the Insurance Committee to read them.

Dr. Sondern read the following:

Regulations Governing Malpractice Defense and Group Adopted by the Executive Committee of the Council of the Medical Society of the State of New York and referred to the House of Delegates for adoption.

MEMBERS NOT INSURED UNDER THE GROUP PLAN

The Medical Society of the State of New York will furnish to its members the services of the Counsel of the Society in actions brought for alleged malpractice, error, or mistake done or elaimed to have been done in the legitimate performance of the duties of their profession as physicians under the following regulations:

The Counsel of the Society will serve as attorney in all actions for alleged malpractice, brought against members in good standing, who must be so certified by its Seere-

tary, excepting as follows:

Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed prior to their admission to mem-

bership in the State Society.

Members shall not be entitled to malpraetice defense if the acts in the suit for which they make application for defense were committed during a period when they were not in good standing, according to Chapter XIV, Section 4, of the By-Laws.

Members shall not be entitled to malpractice defense while residing and/or practicing medicine or surgery outside of the territorial limits of the State of New

York.

The Society will not undertake the defense of any member who, after consideration by the Executive Committee, is believed guilty of criminal abortion, feticide, homicide, or any criminal act or who has not com-

plied with the recognized ethical laws in regard to these

Members shall agree not to compromise any claim against them, nor to make settlement in any manner without the advice or consent of the Society given through its attorney.

In the event that a member sued or threatened with suit shall, without the advice or consent of the attorney of the Society, determine to settle or compromise any claims against him, he shall reimburse the Society for the expense incurred in undertaking his defense, and in default thereof, he shall be deprived of further privileges of malpraetice defense.

The Society shall not assume any responsibility for the payment of any sum agreed upon by arbitration in the settlement of claims, or awarded by court verdicts, or for making payments for any purpose whatsoever.

Members of the Society desiring to avail themselves of

the privileges of this act shall make application therefor in writing to the Secretary of the Society, and it shall be shown to his satisfaction that they are members in good standing. They shall also furnish the Legal Counsel a complete and accurate statement of their connection with, and treatment of, persons upon which complaints against them are based, giving dates of attendance, names and residences of nurses and of other persons cognizant of facts and circumstances necessary to a clear and definite understanding of all matters in question, and shall furnish such other relevant information and execute such papers as may be required of them by the attorney of the State Society.

In the event of any difference of opinion between a member of the Society and the Counsel concerning the eligibility of a claim for defense, or any other matter having to do with malpractice defense or indemnity, all details shall be presented to the Insurance Committee to be referred with recommendations to the Executive Com-

mittee of the Council for its decision.

The foregoing regulations are subject to such change as may from time to time be authorized by the Excentive Committee of the Council or the House of Delegates.

MEMBERS INSURED UNDER THE GROUP PLAN

All members in good standing shall be entitled to malpractice defense and indemnity in the Group Plan of Insurance on payment of the premium due on the policy selected but the amount of insurance protection granted to any member may be limited at the discretion of the Executive Committee of the Council, subject to petition for reconsideration.

When, upon the final completion of the defense of any suit or elaim, it shall appear to the satisfaction of the Executive Committee that the medical procedure, conduct or attitude of the member involved was such that it could not have the approval of competent medical opinion generally and that the continuance of such medical proeedure, conduct or attitude would constitute a burden to the Society's Group Insurance Plan more hazardous than that contemplated in what is generally accepted as the competent practice of medicine, the Society shall have the right to withdraw from such member the privilege of renewal of his indemnity insurance under the Plan. Nothing in this rule shall deny such member a rehearing by the Frenchic Committee. This rule shall deep not ing by the Executive Committee. This rule shall also not abrogate such member's right to subsequent malpractice defense by the Society.

If an assured shall fail to maintain in good standing his membership in the State Society, according to Chapter XIV, Section 4, of the By-Laws, the policy, so far as it applies to such assured, shall be cancelled as of the date upon which he ceased to be a member in good standing. A notice to this effect shall be mailed to the member's last address, and the Company will return upon demand and surrender of his certificate, the uncarned premium due him on account of such cancellation. If the member is reinstated by payment of dues, the former

policy cannot again be put in force but the member can secure a new policy under the same conditions as if he were a new member of the Society. This rule shall become operative if and when it is written into the

policy of the Group Plan.

The Group Plan of Insurauce shall insure a member within the limits of his policy against loss growing out of suits or claims for malpractice, error or mistake, committed or alleged to have been committed by an insured member in the legal practice of his profession or by any assistant of such a member whether in institutional or private practice, in the treatment or care of a patient previously seen and diagnosed by such a member and for whom the member has directed a course of treatment or care.

The Group Plan of Insurance shall not cover the liability of an insured member on account of the use of X-ray for therapeutic treatment, the employment of partners, associates, assistants, technicians or nurses to practice medicine in his name independently of his personal diagnosis and specific instructions as to the treatment or care to be given, nor shall it cover the liability which such a member may have by reason of his ownership in whole or in part of any association, partnership, clinic, hospital, sanitarium, dispensary or any enterprise other than his personal practice of medicine therein. The liability for such ownership constitutes additional hazards not contemplated under the Group policy or rates, and losses on account thereof shall not be charged against these hazards shall, upon request and payment of an additional premium, be furnished by the carrier by endorsement upon member's Group Plan Certificate or under an additional policy of insurance when necessary.

The Group Plan policy shall not cover the liability which an insured member may have on account of injury to patients from causes other than medical treatment, care or advice, nor for injury to persons other than patients from any cause whatsoever. Protection on account of such losses can only be had under general liability or workmen's compensation insurance.

When in the course of duties imposed upon him as a medical officer of the State, or any political sub-division thereof, an insured member shall be required to render medical opinion, he shall he fully protected under his Group Insurance against the consequences of such an opinion provided it shall have been given to competent authority and not made public by him.

All members of the Counties in Greater New York, and Rockland, Westchester, Nassau and Suffolk, desiring insurance protection in the Group plan of the State Society, shall secure that protection through the Authorized Indemnity Representative of the Society, Mr. Harry F. Wanvig.

Members Insureo by Companies Other Than the Carrier of the Group Plan

A member who elects to secure malpractice insurance protection from a company other than the Carrier of the Group Plan shall have the same right of defense by the Counsel of the Medical Society of the State of New York as those members not insured provided said carrier is authorized to do business in the State of New York. If the member desires this service under the circumstances, all the regulations as detailed above applying to members not insured under the Group Plan must be observed. At the time the action is begun and not later the Secretary of the Society shall be furnished with the name of the Insurance Company, policy number, date of policy and amount of insurance carried. There shall also be presented at the same time a letter from an authorized officer of the Insurance Company certifying that the Company will assume the full cost of the defense including the fees of the Counsel of the Medical Society of the State of New York similar to those paid by the Carrier of the Group Plan in like instance. Also

that he shall not be required to consult with or receive instructions from the Company as to the manner of defense and that the Company will accept his opinion on

the final disposition of the action.

As Companies other than the Carrier of the Group Plan usually couped the holders of their policies to accept defense by the Legal Counsel of the Company concerned, the above would not apply. It is essential, however, that members so insured shall also cujoy the benefits of the services of the Counsel of the Medical Society of the State of New York if desired; but it is obvious that such service will be restricted by the rule of the Insurance Company cited above. Thus while the Legal Counsel of the Medical Society of the State of New York cannot be required under these circumstances to assume control of the defense or to appear as associate counsel, he shall be ready to render to the Counsel of the Insurance Company, if requested, a consultant's opinion and advice provided the Company concerned will compensate him for this service in the same manner as the Group Plan Carrier would do if the member was thus insured. All previous resolutions heretofore adopted, pertinent

to malpractice claims and defense, are hereby rescinded. The Vice-Speaker: These resolutions being supplementary to a similar action which has already been considered by the Council, will be referred to the Reference Committee on the Report of the Secretary, Council and

Councillors.

The Vice-Speaker: Any further new business?

14. RESOLUTIONS SPONSORED BY THE EXECUTIVE COMMITTEE

The Secretary: The following resolutions have been approved by the Executive Committee of the Council and referred to the House of Delegates for adoption:

15. CERTIFICATION OF SPECIALISTS (Sec also Sec. 12)

RESOLVEO, That the House of Delegates be requested to authorize the appointment of a Special Committee to study the Certification of Specialists with a view of submitting recommendations and plan of procedure for their certification and registration. (Action, Section 52.)

16. THE JOURNAL

RESOLVEO, That the House of Delegates be requested to authorize the appointment of a Special Committee to study the entire question of the Journal with a viewpoint of submitting recommendation as to organization, form of Journal, finance, and possible profit-making administration. (Action, Section 53.)

17. WORKMEN'S COMPENSATION

RESOLVED. That the House of Delegates be authorized to instruct the President to appoint a committee for the purpose of studying the professional aspects of the Workmen's compensation and to make recommendations to the Executive Committee on the desirability and method of formulating a plan whereby the State Society may set up a basic organization through the constituent local societies for the administration of the professional aspect of the Workmen's Compensation.

The Vice-Speaker: The first two of these resolutions will be referred to Reference Committee on New Business A and the third to Reference Committee on New

Business B.

18. PLAN FOR MEDICAL SERVICES

RESOLVED, That the House of Delegates he requested to authorize the appointment of a Special Committee for the purpose of studying and preparing a plan for medical services throughout the State of New York. (Action, Section 6.4)

The Vice-Speaker: I will refer this to Reference Committee on New Business C. (Report, Section 43.)

19. PRINCIPLES OF PROFESSIONAL CONDUCT

The Secretary: The following is a suggested change in the Principles of Professional Conduct, Section 32.

The Principles of Professional Conduct of the Medical Society of the State of New York shall be amended by adding a new section to be denominated Section 32

(a) to read as follows:

Sec. 32 (a) Physicians shall not participate in the act of the division, transference, assignment, subordination, rebating, splitting, or refunding of any fee for medical or surgical care. Physicians shall not by any subterfuge be a party to such division, transference, assignment, subordination, rebating, splitting or refunding of any fee for medical or surgical care. Nothing in this section, however, shall prohibit the payment of salaries by a qualified physician to other duly qualified persons rendering medical care under his supervision.

The Vice-Speaker: This resolution will also be re-

ferred to Reference Committee on New Business A, they having a similar resolution to consider. (Action,

Section 72.)

20. STATE CONTROL OF CERTIFIED MILK

The Secretary: This is the report of the Special Committee to consider the question of state control of cer-

tified milk.

The Committee recognizes the importance of uniform methods and standards for the production of Certified Milk and it believes these can only be secured by co-operation with the Medical Society of the State of New York, interested County Medical Societies, milk producers, distributors and health departments—but due to lack of information concerning the activities of many milk commissions, no definite steps can be recommended for the improvement and correction of overlapping authority and activity. We recommend that the Execuauthority and activity. We recommend that the Executive Committee of the Mcdical Society of the State of New York forward to the House of Delegates a resolution urging the importance of a committee to further study the situation and report at a subsequent meeting of the Executive Committee.

We also recommend that the following questions be submitted to the Committee for study and report:

1. The desirability of retaining control of the certified Milk Function-this responsibility now being only in the County Medical Societies.

2. A State-wide set-up, with a permanent Executive

and permanent Milk Inspector.

3. A system of bookkeeping to control the situation. The benefits or defects of a Statc-wide Medical Society control and organization.

The Vice-Speaker: This resolution on certified milk is not signed. Is any delegate here, a member of the

Committee responsible?

Dr. Van Kleeck: That was a report of the Special Committee appointed by the President to report to the Executive Committee instructing the Executive Committee to present such a resolution. I was chairman of that committee.

The Vice-Speaker: This resolution will be referred to Reference Committee on New Business C. (Action, Section 40.)

21. PRIZE ESSAYS

The Secretary: There is a report of the Committee on Prize Essays, recommending that the Merrit H. Cash Prize be awarded to the author using the motto "Claude Bernard," and the Lucien Howe Prize to the author using the motto "Watch Your Feet." It is also recommended that the Prize be for \$150.00, \$15.00 of which will be in the form of a bronze medal and the remainder in cash.

On motion duly made and seconded the report was

adopted.

The Secretary opened the envelopes and announced that the winner of the Merrit H. Cash Prize was Dr. H. Hamilton Cooke of Lowville for his Essay on "A Pathological, Experimental, and Clinical Study of Lipoid Deposits in the Gallbladder," and of the Lucien Howe Prize, Dr. Julius Ferber of New York for his Essay on "The Present Status of Thrombo-Angiitis Obliterans with Special Reference to its Treatment by Intravenous Injections."

The Speaker: If the Scorctary has no other new business, I will call for the Reports of the Reference Com-

mittees.

22. Reference Committee on Report of the President (Journal March 1, 1933, page 259)

Dr. Warren of Kings: Your Committee wishes to recognize the honor and the responsibility given to it in surveying the President's Report. The report has been most instructive, for from the beginning to the end, it shows a keen insight into many of the factors embroiling us in our present difficulties.

It appreciates that there is such an intertwining of medicine with organized society, government, and industry that we must study all these in order to understand our own problems better and so to lead better in their solution. All these institutions affect medicinc and medicine must be in close contact with them to influence them. Their fundamental problems are our own primary problems and call for unbiased study to the end that we achieve more stable economic and social security for the future. The report expresses the belief that organized medicine will do its part, and our Society will make such changes as are necessary to keep in consonance with sound development and real progress. We commend this vision of our leader.

23. SUPPLY AND DEMAND OF DOCTORS

The President's report concerns itself first with the facts regarding medical schools and medical matriculants. It states that there are 4,900 doctors graduating a year and 10,000 more young men who are qualified and wish to enter medical schools but who cannot be accommodated. These facts show the tremendous appeal of the idea of a medical career. There are many who would say, "let all who wish to enter medicine do so, do not attempt to discourage a young man or interfere with the planning of his life's work." And they add that slowly this condition will adjust itself, for, as there becomes an over-supply of physicians, the practice of medicine will become less inviting and fewer young men will want to enter the profession. But what happens to medicine in the meantime? The facts are, as gathered from the report of the Lowell Commission, that at this date there are 25,000 physicians in this country in excess of the demand, and it is recognized by all that over-supply of a commodity cheapens it and tends to lower its quality and to undermine its true value. And this is no less true if the commodity happens to be a profession. Who, then, wishes to look forward to our profession lowering standards of service and becoming commercialized through oversupply? Again, when standards are low in a profession, it deters those of better ideals, and high quality and attainment, from entering that field and consequently would deprive medicine of the men of good quality who would otherwise enter. The question finally resolves itself into the latter and allow self into: shall we simply drift in this matter and allow an excess of doctors to graduate yearly, or shall we use our influence and plan to keep out of the pitfalls that such drifting will create: Your Committee feels that this subject is of vital importance and finally

RECOMMENDS that our delegates to the American Medical Association should be instructed to ask for a study to be made by the Committee on Medical Education of the American Medical Association as to the actual yearly need of medical men for our country, and if it find, from that study, that there are more graduates yearly than are needed, it should use its influence to bring about a limitation of the number of medical matriculants and lience of medical graduates

I move that this recommendation be adopted Motion seconded and carried

24 I AN ORGANIZATIONS AND PHYSICIAMS EMPLOYED IN THEM

In contrast to the apparent surplus of doctors throughout the country, the report next speaks of a dearth of medical men engaged in national health organizations and other independent health programs These organizations have nine non medical individuals to every doctor at present occupied in carrying on such work fact calls for reflection, and one asks, would not doctors be of greater assistance in furthering these various health programs? It seems reasonable that medical training should contribute more to programs of this nature than could be expected when they are so dominantly directed by a non medical personnel Why, then, does the situa tion persist? And can there be an adjustment whereby more medical men may he employed to the end that greater efficiency and greater service may be obtained? The object of these agencies is to promote health along one line or another This is also our fundamental purpose, and if we can convince some of these lay and na tional organizations of our sincerity, your Committee feels that there would be an understanding never before realized and eventually they would be converted to the thought that there should be more medical men carrying on activities in their organizations than are at present engaged in them Turthermore, in this way organized medicine would be untlating a forward step in co ordinating and correlating these many activities to the end that finally it might come to direct some if not all of them Your Committee feels that this is a field that should have more careful and detailed study and there

RECOMMENOS that the Commuttee on Public Relations undertake such a study, with the above in mind engaging the interest of some of the larger national and other health agencies and offering our professional experience

and co operation to those organizations

The report next stresses the work of various continuit tees, commissions, foundations, reformers, etc. It states that as reports from these and other bodies have been completed the Executive Committee has subjected them to careful, deliberate, and critical analysis. It states that one report that on the Costs of Medical Care, has been assigned to a special committee to report its findings and recommendations on this matter. Therefore your Committee has no recommendation to make on this part of the report but commends the promptness and dispatch with which these matters have been handled by your President I move the adoption.

Motion seconded and carried

25 Dues and Organization

The next matter taken up by the report dwells at some length on the financial status of our Society. It tells of a disbursement of a dollar a member made to each component society by the Board of Trustees in June 1932. Your Committee commends the spirit of this action in that it shows an understanding of the financial position of many of our members and it displays a willingness to help each one in time of difficulty. Such thoughtful expression serves to weld more securely the parent society to its off-spring Judicious and given in time of difficulty is doubly appreciated. However, the report expresses the thought that even if there are many members of our organization who have difficulty in meeting dues the State Society dues were diminished. We all recognize that organizations are markedly curbing their budgets and further note that many medical organizations have reduced their membership dues. This is reasonable and demanded by the times. It seems to your Committee that we are

brought face to face with one of two alternatives. Shall we reduce the State Society dues or what can the Society do for its members to climinate the rather widespread feeling in favor of a reduction? If we proceed along the first line we must realize that reduction of dues memberetrenchment of activity. In these criterial times when organized medicine is challenged by so many critics it needs money, but more than money it needs a matter to the seems apparent, then that our income should not be diminished. But why we ask ourselves, do more than a few of our members feel that the assessment of the State Society is too high? Certainly ten dollars a year to belong to a great professional organization is a very small amount. And it is a fact that when a man gets what he wants he is willing to pay for it.

If all our members, then, get what they want in the way of help from our organization, there certainly would be no question about paying such a small yearly due Further observation of the matter shows that many of our members complain of the imbility of organized medicine to protect their practice. They eite the lack of a strong active, foreeful campaign against the evermultiplying dispensaries and their abuses. They eite our lack of action when hospitals practice medicine and thes state that we have stood by many years without con certed or effective stand against many abuses of The Workmen's Compensation Law More recently there has been no organized effort th get remuneration for the doc tors who care for the unemployed, although the butcher, the baker and the candle stick maker are naid are a few of the many protests that are launched against medieme from those within its ranks. They fail to ap preciate the many aids that have been at their command But now in time of difficulty they look back and hold medicine responsible for allowing such inroads into their practice that many of them are nearly robbed of livelihood Little wonder, then, that many complum If we could answer the question of why such conditions were not met successfully by organized medicine and adjust ourselves so as to be able in the future to command a more effective solution in handling similar mitters, we could silence the contender for lower Society dues and enlist him in our united front. The report of the Presi dent points the way to such adjustment. It states that there is an insufficient paid personnel. It seems then, to be a matter of organization an organization that will be able to convert recommendations into action. It has long been recognized by all that a great society such as ours cannot possibly function effectively on volunteer help Your Committee feels that the issue could be settled by the answer of one or other of the questions first, shall we reduce dues and retreneli our activities or second shall we continue with our present dies and adjust our organization to such a modern plan as will enable us to

Your Committee unanimously
RECOMMENDS that a committee be appointed to study
our plan of organization to the end that it would become
an effective and efficient one in handling our present
day needs it should be mouded to appeal to and command
the confidence of the people of the State of New York,
and the undivided support and loyalty of the infantry

make proper studies gather facts and effectively and

forceably strive to execute those measures which are rea sonable and right in the conduct of medical matters?

men of our profession—the general practitioners
I move its adoption

Motion seconded and carried

26 ADMINISTRATIVE OFFICER

The Committee further recommends that there should be an administrative officer appointed who should be an employee of the House of Delegates the Council and the Executive Committee of the State Society and whose duty it should be to execute the orders of these bodies and correlate the medical activities of our various standing committees. He should be a full time individual on a salary.

I move its adoption.

Dr. Rooney: I move that we postpone action upon this recommendation until after we have heard the Report of the Reference Committee on the Report of the Committee on Economics, and these two plans be discussed at the same time.

Motion was seconded and carried.

27. INVESTMENT FUND

Furthermore, stressing the need of finances for our organization, the report states that instead of an investment fund of \$145,000 we really need \$500,000. We all realize the money stringency of the present, nevertheless, if we believe that the income expenditure of such a fund would add to the safe-guarding of the health of the people of this state we should make a strenuous effort to organize immediately to that end and continue our efforts until the end is accomplished. Your Committee therefore, recommends that a committee should be appointed to study ways and means for gathering an investment fund from the public with the aim in mind that its yearly income should be expended for the public health and welfare of the people of the State of New York.

I move its adoption. Motion was seconded.

The Vice-Speaker: Is there any further discussion? Are you ready for the question? All those in favor of adopting the recommendation of the Reference Committee in regard to this section of the report signify by saying "aye" . . . those opposed by saying "no."

Motion is lost.

28. Tribute to Dr. John Card

Your President next reminds us of the loss of the distinguished Speaker of this House, Dr. John Card. Your Committee commends the spirit of tribute given in the report to this able leader and recommends that there be spread in the minutes of our meeting an expression of appreciation of the able service rendered to this House for a period of eight years by a most able, loyal, enthusiastic and conscientious officer.

Motion seconded and carried. (See Section 74.)

29. Consolidation of Committees on Physio Therapy, Public Health and Periodic Health Examination

Reference is next made to the consolidation of the Committees on Physio Therapy and Periodic Health Examinations with the Public Health and Medical Education Committee. Your Committee commends the centralization of effort and the elimination of duplicate activity with

its unnecessary expense.

The report next commends the untiring effort and effective work of the Legislative Committee and the Committee on Medical Research. It expresses appreciation, to all members of these Committees and to their chairmen, of their handling of all matters in their domain in a most capable and efficient way. Your Committee has no recommendation but wishes to express its appreciation of the able service given by these committees and their chairmen, with the feeling that every member of our Society is indebted to these gentlemen for their effort and their ability in guiding the matters detailed to them in such a manner that their action has been a credit to organized medicine.

30. GRADUATE INSTRUCTION

It next stresses the organization of graduate instruction under the Committee on Public Health and Medical Education. It is recognized that there are all varieties of medical instruction. It is a proven fact that now the practitioner wishes his medical instruction to be given to him in such a way that he can apply it to his daily problems. Your committee strongly recommends that this work of graduate medical instruction should he con-

tinued and amplified, stressing the practical application of the subjects dealt with.

I move its adoption.

Motion seconded and carried.

31. GOVERNOR'S COMMISSION ON WORKMEN'S COMPENSATION

The report next takes up the matter of the Governor's Commission, appointed to study some of the abuses of the Workmen's Compensation Law. This Commission is to make a complete, unbiased study of the Workmen's Compensation Law with the idea of ultimately making such changes as the study discloses should be made to eliminate some of the abuses of its administration. Again your Committee commends the activity and promptness of the President in having this matter speedily reviewed, and, as a recommendation will be made through the Committee on Economics none, will be made here.

32. MAINTAINING ORGANIZATION SOLIDARITY OF COUNTY SOCIETIES AND STATE SOCIETY

We then pass in the report to the statement that "certain component societies have a tendency to initiate certain movements within their ranks without due regard to the State Society." Such movements hardly seem possible. We all know there are defined, in the Constitution and By-laws of the State Society, its relation to the com-ponent societies, and again the component societies have in their Constitution and By-laws explicit statements as to their full relationship to the parent Society. It seems, then, there should be no misunderstanding about movements on the part of either body which would divide the prestige or strength of either society. However, it is recognized that there are problems individual to societies, as conditions calling for action may prevail in a metropolitan area that might not be possible in a rural section. Thought on such problems must not be stifled, for the more thought, study and strength that any one component society develops the greater will be the strength and force of its parent society. There must, however, be a complete recognition of authority in organization or else that organization crumbles. It seems to your Committee, then, that the general statement above mentioned in this report can reach an amicable understanding in the following recommendation. If any component society has problems individual to itself it should not act on such problems inde-pendently if such action is contrary, either in spirit or word, to its recognized relationship to the parent society without first presenting its problems, with recommenda-tions, to the House of Delegates, to The Council, or to The Executive Committee for discussion and disposition.

I move its adoption.

Motion seconded and carried.

33. LEGAL DEFENSE, ORGANIZATION AND INDEMNITY

Dr. Warren of Kings: Malpractice and malpractice protection are referred to next in the report. It states that nine out of every one hundred members are or will be sued for malpractice. It stresses the need for legal defense and protection, and expounds the principle that defense and indemnity should go hand in hand. There are many of our members who buy other protective insurance, and then look to our Society for defense when trouble comes. They spend their money elsewhere and then wish to have our Society spend its money to protect them. This attitude is not conductive to medico-legal solidarity. Through vears of continued thoughtful study of this matter the Medical Society of the State of New York has made available protection insurance to our group, through a recognized company, giving ample security and at a reasonable rate. It seems that, under the circumstances, every member would welcome the opportunity of participating in the State group plan, rather than to remain an outsider. It seems axiomatic

that wherever or from whom one obtains insurance he would look to that source for protection, and your Committee therefore recommends that the Medical Society of the State of New York should assume the responsibility of legal defense in malpractice suits to those members only who earry insurance in the State Society group plan.

I move its adoption.

Motion seconded.

Dr. Rooney: I move, as a substitute motion that this recommendation of the Reference Committee he post-poned until the Reference Committee on the report of the Council has presented its report, because there is subject matter in the report of the Council that is pertinent, and that should be discussed, in my opinion, at the same time that discussion arises upon this section.

This motion was seconded and carried.

34. TRIBUTE TO STAFF WORKERS

Dr. Warren of Kings: The President's report goes on to express his personal appreciation to all the members of the Society's office staff in New York City, for the aid and cooperation given him during the past year. In particular he mentions the nost valuable help given by our secretaries Dr. Dougherty and Dr. Irving. Your Committee feels that it cannot allow this occasion to pass without registering its appreciation for the untiring effort and the unswerving loyalty which these individuals have given our Society for many years, and for which every incomber of this House is duly grateful.

35. STATEMENT OF WORK DONE

Finally the report expresses the regret of the President in his inability to accomplish all that had been planned. It recognizes that a year is too short to do much with the tremendous issues that have faced medicine. It mentions that whatever has been done the Medical Society of the State of New York has been true to its tradition and history, and in spite of every adverse condition it has maintained the ideals for which it has always stood. Your Committee heartily agrees with this thought of the report and wishes to record its belief that much has been accomplished and many seeds have been sown during the past year that will bear fruit in the future. We believe that we have lived in the strength and wisdom of a real leader and will continue to live under the influence of his effort for many years to

I move you the adoption of the report as a whole with the exception of the section that was postponed and the section that was defeated.

Motion seconded and carried.

36. Report of the Reference Committee on the Reports of the Committees on Arrangements and on Scientific Work

The Vice-Speaker: Dr. Kosmak will read the report of the Reference Committee on the Reports of the Committees on Arrangements and on Scientific Work.

Dr. Kosmak: The report of the Committee on Arragenents speaks for itself through the material evidence which is afforded by the extensive and interesting program for the instruction and entertainment of the visitors to this year's meeting. We desire to commend in particular the innovation of having several guest speakers of the Delegates' Dinner discuss certain topics of vital interest to the profession. The Open Forum meeting constitutes another feature, the outcome of which will be awaited with interest. Dr. Samuel J. Kopetzky, the Chairman of the Committee and his colleagues are deserving of thanks and appreciation for their outstanding labors in the effort to make a signal success of this year's meeting of our Society.

37. COMMITTEE ON SCIENTIFIC WORK

Your Reference Committee has also been delegated to consider the Report of the Committee on Scientific Work, Under the leadership of its very capable Chairman Dr. Arthur J. Bedell, an excellent program of well closen topics has been developed in the various sections. The innovation for this year is the symposium on "Dental Conditions as They Affect General Health," developed in cooperation with some of the members of the dental profession. The Scientific Exhibit, begun last year, has been greatly enlarged and ably arranged by Dr. Frederic E. Soudern and, it is hoped, may constitute a pear, the feature of the Society's anunal meeting. A "Clinical Day" has likewise been inaugurated, the success of which will be measured by the attendance at the various hospitals which have cooperated in this program.

The Committee on Scientific Work deserves the unstinted praise of our Society for carrying out the difficult task assigned to it and upon which so much of

the success of the meeting depends.

I move the adoption of this report.

Motion seconded and carried.

38. FEE-SPLITTING (Section 8)

Dr. Winslow: The Reference Committee on New Business C reports that during the year 1932 the Committee on Civic Policy of the Medical Society of the Committee on Civic Policy of the Medical Society of the Committee of New York made an exhaustive study of the problem of the secret division of fees, popularly known as secret fee-splitting. It held a number of open meetings at which many prominent physicians and surgeous, as well as others interested in the practice of medicine from the hospital and administrative standpoint, submitted their opinions on this question.

At least four open meetings were devoted to the taking of testimony, while at other meetings the Committee

itself wrestled with this difficult problem.

As the result of their deliberations, the Committee on Civic Policy came to the conclusion that the essential cause of fee-splitting was in all probability economic. They felt that the great majority of young medical men began practice with the highest professional ideals, but for one reason or another, many of these younger men, particularly in the larger cities, began the practice of the secret division of fees. The chical family practitioner is often so poorly paid in comparison with the surgeon or specialist, particularly in normal times, as to make it difficult for him to carn a decent living.

The Committee recognized fully the evils of secret feesplitting, the corrupting influence on the practitioner and the specialist, the possibility of a betrayal of a patient through reference to an inferior surgeon on specialist because of his willingness to indulge in the practice of secret fee-splitting. The influence of secret fee-splitting on the younger surgeon and specialist in building up a specialty practice was particularly noted. The inimical results of secret fee-splitting on the public hecause of the referring of the public to men of lesser ability due to their willingness to split fees is an important factor in the consideration of this problem. The Committee was unanimous in condemning all forms of secret fee-splitting, commissions and rebates.

In order to cope with the existing evil and, if possible, to lessen or control it, the Committee made the following recommendations to the Comitia Minora of the Medical Society of the County of New York, which were accepted by it and finally adopted by that Society at a stated meeting.

"1. The Comitia Minora condemns the practice of the secret division of fees in the strongest possible terms."

I move its adoption,

Motion seconded and carried.

Dr. Winslow: 2. The Comitia Minora calls upon con-

sulting specialists and surgoons to join with the County Society in the education of the public by explaining to patients and their families the nature and value of the family physician's scrvices before, during and after operation, and the necessity for his proper compensation.

I move its adoption.

Motion seconded and carried.

Dr. Winslow: 3. Where essential pre-operative and post-operative service is rendered by the family physician in a surgical case, an adequate fee should be paid to him for this service. In the opinion of the Comitia, it is desirable that the family physician's bill for this service be rendered at the same time as the bill of the surgeon, in order to establish in the patient's mind the essential importance of both services.

I move its adoption,

Motion seconded and carried.

Dr. Winslow: 4. A joint bill may be rendered to a patient for the combined services of physicians and surgeons participating in the conduct of a case, and shall specify the sum allocated to each participant as well as the total amount.

The Comitia Minora disapproves of any joint bill which does not specify the sums allocated to each participant in a given ease.

In view of the importance of the problem of secret fee-splitting to the public and to the profession alike, we respectfully memorialize the Medical Society of the State of New York, in convention assembled, to endorse the recommendations proposed by the Medical Society of the County of New York, and we call upon the convention to suggest such steps as will lead to the adoption of these principles of professional conduct as an integral part of the Principles of Professional Conduct of the Medical Society of the State of New York.

Your committee disapproves of number 4 and I move the disapproval by this society.

The motion was seconded.

The Vice-Speaker: The Reference Committee recommends that section four of the report be disapproved. If you vote in the affirmative you are supporting the Reference Committee in disapproving of this resolution. All those in favor of adopting the report of the Reference Committee disapproving the joint bill proposition, signify by saying "aye"—those opposed "no." The "ayes" have it. The Reference Committee is sustained and the disapproval of Section 4 of the resolution is confirmed.

39. Nurse Anesthetist (Section 7)

Dr. Winslow: The next resolution is on the nurse anesthetist. In the preamble there are twelve statements and two resolutions. You have heard the statements read. The resolutions are as follows:

Resolved that the Medical Society of the State of New York affirm that the giving of an anesthetic constitutes the practice of medicine and insist on the strict observance of the provisions of the Medical Practice Act without subterfuge or evasion.

I move its adoption.

Motion seconded and carried.

Dr. Winslow: Resolved that if it is the opinion of the Attorney-General that non-medical technicians practicing anesthesia are not violating the law under present conditions, that the proper procedure be instituted to obtain legislation which will include anesthesia in the practice of medicine or limit the administration of anesthesia to duly licensed dentists or physicians.

I move its adoption.

nd carried.

40. STATE CONTROL OF CERTIFIED MILK (Section 20)

Dr. Winslow: The Committee recognizes the importance of uniform methods and standards for the production of Certified Milk and it believes these can only be seeured by cooperation with the Medical Society of the State of New York, interested County Medical Societies, milk producers, distributors and health departments. But due to lack of information concerning the activities of many milk commissions, no definite steps can be recommended for the improvement and correction of overlapping authority and activity. We recommend the Executive Committee of the Medical Society of the State of New York forward to the House of Delegates a resolution urging the importance of a committee to further study the situation and report at a subsequent meeting of the Executive Committee.

I move its adoption.

Motion seconded and carried.

Dr. Winslow: We recommend that the following questions be submitted to the committee for study and report:

- 1. The desirability of retaining control of the Certified Milk Function—this responsibility now being only in the County Medical Societies.
- 2. A State-wide set-up, with a permanent Executive and permanent Milk Inspector.
 - 3. A system of bookkeeping to control the situation.
- 4. The benefits or defects of a State-wide Medical Society control and organization.

I move its adoption.

Motion seconded and carried.

41. CERTIFICATION OF SPECIALISTS (Section 12)

Dr. IVinslow: Whereas, the American Board for Ophthalmic Examinations, the American Board of Oto-Laryngology, the American Board of Obstetries and Gynecology and the American Board of Dermatology and Syphilology have been organized by their respective National Societies, together with the corresponding scientific Scetions of the American Medical Association, have functioned successfully under the supervision of the parent bodies, and have been endowed with the prestige of the sponsoring societies, and

WHEREAS, at least two additional special groups are contemplating the creation of similar Boards in the near future, and

WHEREAS, the efforts made by the existing Boards to certify well qualified specialists have met with the approval of the medical profession at large, and

WHEREAS, the personnel of such examining Boards is best selected by the sponsoring National Societics, and

Whereas, the autonomy and independence of each of the special Board are essential to preclude political domination or control by extraneous influences, therefore

BE IT RESOLVED, that the House of Delegates of the Medical Society of the State of New York instruct its delegates to the American Medical Association, at the meeting in Milwaukee in June, 1933, to further any and all Resolutions which have for their purpose the advancement of these well established efforts to eertify well qualified specialists, and to oppose any and all Resolutions which have for their purpose interference with the constituted authority and activities of the Special Examining Boards as they now exist.

I move its adoption.

Motion seconded and carried.

Dr. Winslow: I move the adoption of the report as a whole.

Motion seconded and carried.

42. RETIRED MEMBERS

The Secretary: I have on my desk the names of a number of physicians that have been recommended to the State Society by their respective County Societies

for election to retired membership.

Moses Aronson, New York; Edward L. Ayme, New York; Willis G. Babcock, Cleveland; Elias H. Bartley, Brooklyn; J. T. Joseph Bird, New York; John W. Brannan, New York; Garrison Lee Brnwu, Euclid; William S. Bryant, New York; Clark Burnham, Brooklyn; Charles L. Dana, New York; Frederic de Kraft, New York; Frederic S Dennis, New York; A. Wilson Dods, Fredonia: John E. Dusseldorf Brooklyn; Hiram Elliott donia; John E. Dusseldorf, Brooklyn; Hiram Elliott, donia; John E. Dusseldorf, Brooklyn; Hiram Élliott, Brooklyn; Albert H. Ely, New York; Myron C. Hawley, Randolph; John A. Jackson, New York; William B. Johnston, Ellicottville; William M. Keen, New York; Isabel T. MacMillau, New York; George H. Pierce, Brooklyn; Sigmund Pollitzer, New York; Hirsch Rabinowitsch, New York; Nelson G. Richmond, Fredonia David Robert Rodger, Richmond Hill; George L. Rood, Etna; John Clarence Sharp, New York; Henry M. Silver, New York; Gustav H. E. Starke, Glen Ridge, N. J.; Franklin M. Stephens, New York; Frank H. Stephenson, Cazennvia; Benjamin S. Swetland, Brocton; Mathilda K. Wallin, Elmsford; J. Zinmerman Wild, Brooklyn; Adolph Zeli, New York; Frank Reynolds, Onondaga. Frank Reynolds, Onondaga.

The Secretary: I move these names he placed on the retired list.

Motion seconded and carried.

The Vice-Speaker: Have you any further report to make?

43. PLAN OF MEDICAL SERVICE (Section 18)

Dr. Elliott: Reference Committee on New Business C. WHEREAS, various reports from lay and medical societies regarding practice of medicine suggest the desirability of the State Society undertaking a comprehensive study for the purpose of ontlining a plan of medical service for the state—an example worthy of study being the report of the British Medical Society, entitled "Medical Service for the Nation,"—be it resolved that the House of Delegates authorize the appointment of a special committee of five by the president for the purpose of studying and preparing a plan of medical service for the peo-ple of the State of New York.

I move that the resolution be adopted.

Dr. Rooney: I move that the discussion on this ques-Dr. Rooney: I move that the discussion on this question presented by the Chairman of this Committee be postponed and discussed at the same time as the discussion of the report of the Reference Committee on the Report of the Committee on the Costs of Medical Care. Motion seconded and carried. (Action, Section 64.)

44. AMENDMENT TO BY-LAWS-DISTRICT BRANCHES

Dr. Goodrich presented the following resolution: Amend the By-Laws, Chapter 8, Section I.

Delete in line twenty-six of the second paragraph the words "not to exceed \$200.00" and insert in their place the following:

"A sum to be determined on a per capita basis of membership by recommendation of the Executive Committee and final determination by the Board of Trustees. The Secretary: As this is an amendment to the By-

Laws it will have to lay over for a year.

45. Allocation to District Branches (Section 9)

Dr. Jennings of Kings: Reference Committee on New Business B. Whereas, since due to the present economic conditions, the several District Branches and their com-

ponent County Societies have great difficulty in balancing their budgets; and in praviding finids for such purposes as carrying on their rolls and otherwise assisting indigent members, previously in good standing; and in order to avoid the necessity of retrenchment of normal standard activities of the District Branches and County Societies therefore-BE IT RESOLVED that the Executive Committee and the

Board of Trustees be requested to allocate Three Dollars (\$3.00) per member back to the District Branches for such utilization as in their judgment may be wise. I recommend its adoption.

Motion was seconded.

A discussion followed and the motion was lost.

46. Section on Urology

(Scetion 11)

Dr. Jennings: The undersigned, having especial interest in the science and art of Urology, respectfully petition our State Society to establish a section to be known as the Section on Urology.

It is recommended by the Reference Committee a Section on Urology be established.

The motion was seconded and carried.

47. SECTION ON PHYSICAL THERAPY AND RADIOLOGY (Section 11)

Dr. Jennings: 1. Be it resolved that the Society make a petition to the Executive Committee of the Medical Society of the State of New York, asking for the establishment of a Section on Physical Therapy, which could be conveniently combined with that on Radiology, and the time equally divided between the two divisions.

The Committee recommends that this petition be denied. The motion was seconded and carried.

For further action see Section 67.

48. REPORT OF THE REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON PUBLIC RELATIONS

(Journal March 1, page 272)

Dr. Howland: We commend the Public Relations Committee for their extreme zeal, activity and enthusiasm in carrying out their work in endeavoring to provide the public with the best medical and public health service possible.

First, the prime objective being to create harmony among medical and public health workers.

Second, aiding the public to recognize good medical scrvice.

Third, by stimulating physicians to become active members in all public movements in health and welfare and to take a leading part in public health activities.

We endorse their stand in leaving the technique of carrying out this program to each county unit.

We believe the best method to further this project is that they continue their regional conferences.

We endorse their stand on free school and school examinations.

We recommend further study relative to venercal

disease control.

This committee approves of the Public Relation's Committee's stand relative to the correction of the abuse of full time physicians employed by the state entering the private practice of medicine.

We recommend a continuation of the conferences with the Medical Inspection Bureau of the State Department of Education with reference to free school and school examinations, cooperating with the Medical Inspection Bureau of the State Department nf Health, in relation to the anti-tuberculosis work in the schools of the state. We recommend that the county unit take a more active part in this work.

We favor the continuation of sending Bulletins to

various county society committees.

We favor the continuation of the lectures before medical student bodies throughout the state on organized medicine, medical laws and medical ethics.

I move its adoption.

Motion seconded and carried.

49. Committee on Revision of Constitution

Dr. Browder of Kings, presented the following resolution:

WHEREAS, times change and we change with them, and whereas certain modifications of organization become

at times desirable,

THEREFORE BE IT RESOLVED that the Speaker of this House of Delegates of the Medical Society of the State of New York is empowered and directed to appoint from this House a committee consisting of one member from each District Branch and a chairman to prepare a Revised Constitution and present such revision to the next meeting of the House of Delegates.

The Vice-Speaker: This resolution will be referred

to Reference Committee on New Business A. (Action,

Section 73.)

50. RACIAL DISCRIMINATION (Section 6)

Dr. Sobel: Reference Committee on New Business A. The Medical Society of the State of New York believes that there should not be nationality in science or medical progress and it views with concern any policies at any time or in any place that tend to discriminate between

professional men in terms of race or creed.

I move its adoption.

Motion seconded and carried.

51. Woman's Auxiliary

(Section 10)

Whereas, the American Medical Association at its meeting in St. Louis in 1922 endorsed the motion for the formation of a Woman's Auxiliary to the American Medical Association, and

Whereas, in July, 1932, there were thirty-six State Auxiliaries and the District of Columbia Auxiliary in addition to a County Auxiliary in each of two States functioning as State Auxiliaries; and

WHEREAS, a Woman's Auxiliary to the Medical Society of the County of Queens has been formed and is func-tioning, therefore, be it

RESOLVED, that it is the sense of this meeting that a Woman's Auxiliary to the Medical Society of the State of New York be formed and that the Woman's Auxiliary to the Medical Society of the County of Queens be endorsed and requested to function as the nucleus of the New York State Auxiliary, with five (5) Members of the State Society to be appointed by the President and these five members shall aet as a Council for the guidance of this Auxiliary.

Your Reference Committee disapproves of the resolution as read, but approves of it if it ends at the word

"formed," in paragraph four. Motion seconded and carried.

52. CERTIFICATION OF SPECIALISTS (Section 15)

Dr. Sobel: Resolved that the House of Delegates be requested to authorize the appointment of a Special Committee to study the certification of specialists with a view of submitting recommendations and plan of procedure for their certification or registration

I move its adoption.

Dr. Kasmak: This is unnecessary. I do not see any need for a resolution of that kind. The National Bodies

have already taken up the question of specialization in their own field. This Society has recognized that by the purport of the resolution which it has asked its delegates to the American Medical Association to endorse.

The Vice-Speaker: Dr. Kosmak makes the point this is a superfluous resolution. Therefore, if you approve of the recommendation of your Reference Committee you will vote "aye," otherwise "no."

The motion is lost.

53. THE JOURNAL (Section 16)

Dr. Sobel: Resolved that the House of Delegates be requested to authorize the appointment of a Special Committee to study the entire question of the Journal, with a viewpoint of submitting recommendations as to organization, form of Journal, finances, and possible profitmaking administration.

I move its adoption.

Motion seconded and carried. (See also Section 58.)

54. PRINCIPLES OF PROFESSIONAL CONDUCT

Dr. Sobel: The Principles of Professional Conduct of the Medical Society of the State of New York shall be amended by adding a new section to be denominated Section 32 (a) to read as follows:

Section 32 (a) Physicians shall not participate in the

act of the division, transference, assignment, subordination, rebating, splitting, or refunding of any fee for medical or surgical care. Physicians shall not by any subterfuge be a party to such division, transference, as signment, subordination, relating, splitting or refunding of any fee for medical or surgical care. Nothing in this scetion, however, shall prohibit the payment of salaries by a qualified physician to other duly qualified persons rendering medical care under his supervision.

Reference Committee A on New Business recommends the substitution of proposed section 32 (a) for present

section 32 as now standing.

Dr. Rooney: As there seems to be some confusion as to whether this is a substitute for the present Section 32 or an addition to the same, I move that the resolution he re-referred to the committee to consult with counsel and rewrite this section and then report to this house.

Motion seconded and carried. (Action, Section 72.)

Dr. Sobel: I move the adoption of the remainder of

the report as read.

Motion seconded and carried.

55. TRUSTEES REPORT

(Journal, March 1, 1933, page 269)

Dr. Cumiffe: The Reference Committee is very much much pleased with the attitude of our Trustees in conserving the resources and maintaining a balanced budget, so that the financial condition of this Society remains satisfactory at the close of the year, 1932.

We note with pleasure, the increase in the value of our investments during the year to the amount of \$7,838.75, also ten \$1,000.00 United States Treasury Bonds were purchased and added to the investment fund, which now totals \$104,401.50. We endorse their recommendation to continue the policy of annually augmenting this investment fund,

I move its adoption.

Motion seconded and carried.

56. Annual Dues

Dr. Cunnifie: The Committee also concurs in their suggestion that all delegates proposing new activities which involve the expenditure of funds, should carefully consider the ultimate cost to the Society. We note that an analysis of the disbursement of the members annual dues, shows that less than 80 cents go to the investment fund, and we endorse their recommendation that the present annual dues be maintained.

Dr. Kosmak: Do I understand that there is a motion before the House to accept this recommendation?

The Vice-Speaker: Yes.

Dr. Kosmak: I would like to speak against it and offer as a substitute motion that this particular subject be reserved for separate consideration at some subsequent time.

The Fice-Speaker: The motion has been made to

postpone consideration of this report.

Motion seconded.

Dr. Rooney: Why can't we settle it now? It is going to take up plenty of time tonight to discuss the reports of two important committees. 1 am against the substitute motion.

A vote was thereupon taken.
The Vice-Speaker: The motion is lost and the report is now before you. Is there any further discussion of the recommendation of the Reference Committee endorsing the recommendation of the Trustees that the present dues to the State Society be maintained? That is the question that is now before you.
The Vice-Speaker: Are you ready for the question?

A vote was taken and the motion was carried,

Dr. Cunnifie: The Committee congratulates the Board of Trustees on their efficient work during the past year, and commends them most highly for their excellent work.

I move the acceptance of the report as a whole.

Motion seconded and carried.

57. REPORT OF REFERENCE COMMITTEE ON REPORT OF TREASURER (Journal, March 1, 1933, page 270)

Dr. Cumiffe: We have carefully studied both the balance sheet as of December 31, 1932, and the statement of income and expense for the twelve months ending at

the same date. We find the statements accurate and a very efficient analysis of our financial transactions during the year 1932. We commend the Treasurer for his efficient and

diligent work in this office.

move the adoption of this portion of the report. Motion seconded and carried.

58. THE JOURNAL

Dr. Cunniffe: However, there are two items which we think deserve special consideration at this time, note that the deficit in the financial statement of the Journal's income and expense account is \$9,316.13, and the income from dues allocated to the Journal was \$12,330,00, making a total expense of \$21,646.13 for the

publishing of the Journal.

We recommend that the President be instructed to appoint a committee of five, to study the matter of the publishing of the Journal. Said Committee to report its recommendations back to the Council not later than

September 15, 1933.

recommend the adoption of this portion of the report. Motion seconded and carried. See also Section 53.

59. THE DIRECTORY

Dr. Cunniffe: The second item is in relation to the publishing of our directory. We find that the net cost of the directory is \$1,285.57, and the amount allocated from the dues of our members is \$12,330,00, making the cost of our directory \$13,615.57 annually. We recommend that in the future the directory be not published annually, but every second year.

I move the adoption of that portion of the report.

Dr. Rooney: I move that this section of the report

be tabled.

The Vice-Speaker: The motion has been made to table the report on the subject of the directory.

A vote was thereupon taken.

The Vice-Speaker: Division has been called for. All those in favor of laying that part of this recom-

mendation on the table please rise.

All those opposed please rise. The motion is carried 71 to 18.

Dr. Cumific: I seem to misunderstand this motion. Part of this report has already been accepted. The report was accepted to a point that the committee of five

The Vice-Speaker: That is right.

Dr. Cunnific: And the only part that is to be tabled is the part of the report having to do with the Directory. The Journal was accepted.

Dr. Rooney: May I state the intent of my motion? It related only to that section of the report that speaks about the time of publication of the Directory. It had no reference to the preceding part of the recommenda-tion that concerned the appointment of the committee of five to study the Journal and to make a report. As a matter of fact, the chairman having made that motion for adoption, I will second his motion to adopt.

The Vice-Speaker: It was adopted.

Dr. Goodrich: On a point of information, wasn't the Reference Committee's report-another Reference Committee's report a short time ago adopted also appointing The Secretary: Yes, it was.

Dr. Goodrich: I move you, sir, that these committees

be one and the same.

The Vice-Speaker: The motion before the House is that in view of the fact we have already approved a recommendation of another Reference Committee recnmmending the appointment of a committee of five that these two committees be one and the same.

Motion seconded and carried.

Dr. Cunniffe: I move the acceptance of the entire report with the exception of the last paragraph dealing with the Directory.

Motion seconded and carried.

60. REPORT OF REFERENCE COMMITTEE ON REPORT OF LEGAL COUNSEL

Dr. Hambrook: We wish to call attention to the increasing amount of work performed by the Legal Department of this Society, and while the report this year covers a period of only eleven months, the same number of cases were instituted as during the preceding year. Mr. Lorenz J. Brosnan, our Counsel, is ably assisted by his associates, Mr. Thomas H. Clearwater and Mr. Willisan F. Martin, and with a very efficient office force, the work assigned to the legal Counsel has been performed in a creditable manner. Due recognition is given to the able cooperation of the Officers of the Medical Society of the State of New York,

We wish to emphasize again the great number of malpractice actions being instituted against members of the medical profession, and the need of proper protec-tion against such actions. The former Chairman of the Insurance Committee, the late Dr. John A. Card, worked earnestly to perfect the group plan of insurance, and his successor, Dr. Frederic E. Sondern, has carried on the work of the Committee in a very efficient manner.

Of the 292 cases instituted during the eleven months,

188 eases were disposed of; 28 have been settled and in 153 cases either judgments for the defendants have been secured after trial, or they have been disposed of through dismissal, discontinuance, or abatement. In 7 cases only, was judgment rendered in favor of the plaintiff, and 3 of these cases are pending on appeal. This brief summary gives some idea of the amount of work being handled by our Legal Department and the efficient man-ner in which it is being accomplished.

The editorials during the year have been of the same high standard, very instructive to the members, and on a variety of subjects. The Committee feels that more attention should be given to these articles and the information contained therein should be compiled and printed in some way for permanent reference.

In conclusion, the Committee again wishes to emphasize the great importance of the group plan of insurance and the growing need for protection of the medical profession against malpractice actions. Our Legal Department is in every way worthy of our commendation and confidence.

I move the adoption of the report. Motion seconded and carried.

61. Recess

The Secretary: I move that this House adjourn until a quarter before nine o'clock.

Motion seconded and carried.

EVENING SESSION-8:45 P.M.

62. Special Committee on Costs of Medical Care

The meeting was called to order by the Speaker at 8:45 P.M.

The Speaker: We will proceed with the business of the House. Are there any resolutions to be offered?

Vice-Speaker: Under a resolution adopted this afternoon, the first order of business tonight is the consideration of the report of the Committee on the Costs of Medical Care. Is Dr. Booth ready to present his Report?

Medical Care. Is Dr. Booth ready to present his Report?

Dr. Kopetsky of New York: I move that the consideration of Dr. Booth's Report be referred to this House of Delegates sitting as a Committee of The Whole.

Motion seconded.

The Vice-Speaker: The motion has been made and seconded that we go into a Committee of The Whole for a consideration of this report rather than refer it to an ordinary Reference Committee.

Motion carried.

The Vice-Speaker: We will go into a Committee of The Whole. Under parliamentary usage the maker of the motion becomes chairman of the committee and I will ask Dr. Leitner of Rockland to act as sergeant-atarms to see that none are present who are not members

of the Medical Society of the State of New York.

There are some of the doctors who have come down here to listen to this discussion and Dr. Heyd has asked me to allow them this privilege. If you wish the men who are not delegates to be excluded, that is your

privilege.

Dr. Rooney: There is no provision by which the resolution of a parliamentary body sitting as a Committee of The Whole means executive session. It is not executive session. I feel the direction of the Speaker is quite in order, that the members of this Society may listen to, but not participate in the debate, all who are not members of the Society should be excluded from the room.

Dr. Kopetsky, Chairman of the Committee of The Whole: We are assembled as a Committee of The Whole to hear the report of a Special Committee appointed by the President to consider the report of the Committee on the Costs of Medical Care and the report of the Commission on Medical Education.

Dr. Booth read the following report:

To the House of Delegates:

Your Committee, after giving the matters before us careful consideration, is prompted to reiterate the truism that both the problem of quality of medical care and the problem of distribution of medical service are questions for the consideration of organized medicine. Your Committee believes that the Medical Society of the State of New York is the competent body to suggest measures and remedies for medical services in this State, and that the professional aspects of these problems can in the long run be administered adequately, and the remedies

suggested can be made only by a personnel that by training and experience is competent to do the work. To place regulation and distribution of medical service in the hands of non-professional bodies usually results in an overwhelming increase in bureaueracy and a resultant augmented tax rate. Your Committee can find nothing in history or experience that obligates a community to give a perfectability of service simply because a part of the community demands it, when the costs would be beyond the ability of the community to bear.

Holding these views, we first present our general comments on the reports before us, and then offer substitute recommendations for your careful consideration.

GENERAL CONSIDERATIONS

When it is considered that the Committee on the Costs of Medical Care has been five years on its survey, and has expended a sum of money considerably over \$800,000, its final report is an extremely disappointing and empty document. The data assembled under its supervision are both interesting and informative, but they hardly required so much time or so much money for their compilation.

In the interpretation and correlation of the data in these miscellaneous reports there is much that we question. It is significant that a Committee with a total membership of 48 should have had to submit five separate reports. The controversy provoked in the Committee itself by the recommendations in the majority report do not lend an air of authority to them or hold out unqualified hopes of success for the projects advocated.

fied hopes of success for the projects advocated.

It appears too that the leaders of the Committee set ont with a distinct bias for some of the proposals urged so enthusiastically in the majority report. Thus, group practice appears to have been from the start a pet idea of the directing forces in the Committee. This finds support in the fact that the Committee uses as its examples a few outstandingly successful organizations for group practice, but ignores the many instances in which

such groups were not successful.

Another point on which there appears to have been a definite bias is the apparent desire of the Committee to place control of the practice of medicine in the hands of social agencies. The majority report creates the impression that the medical profession is unprogressive and stands in the way of effective reforms in the distribution of professional services. All of its projects involve the establishment of elaborate superstructures about the physicians, who, after all, are the principal agents in any medical project. Even in the recommendations for group practice the majority report makes only casual mention of the county medical society clinics, and merely suggests them as possibilities for rural areas or small towns, although a number of medical societies throughout the country have undertaken work along these lines.

The Committee's drastic recommendations for group practice and for health insurance—whether voluntary or compulsory—are based upon opinion rather than fact. Over and against the evils which they admit have heretofore inhered in medical practice by organizations under insurance systems and by governmental health services, they state the mere opinion, unsubstantiated by any concrete facts, that these evils will cease to exist if the methods referred to are put into general effect here. The majority report opposes compulsory health insurance because of its unsatisfactory results in Europe and its inapplicability to American conditions, and then goes on to urge voluntary health insurance, which it repeatedly states to be the forerunner of compulsory health insurance.

The Committee emphasizes the indispensability of the personal relationship between doctor and patient, and then proceeds to urge systems of practice which must inevitably destroy that personal relationship.

The entire trend of the majority report appears to be theoretical and visionary, rather than practical and con-

crete. Without specifying exactly what it considers adequate medical care to be, it implies an exaggerated and extravagant standard of medical care. Its attitude toward preventive medicine, for example, is highly theoretical and implies that it is possible to prevent a greater percentage of illness than actually can be prevented with our present knowledge. Under the present method of medical practice, which the Committee considers inetfective and inefficient, every preventive method of specific value has been put into effect with striking results (e.g., prevention of smallpox, typhoid, hookworm, diphtheria, etc.).

No amount of organization is going to prevent disease unless we actually have substantial prophylactic measures to employ. Failure to employ preventive service is not due primarily to the individualistic state of medical practice, but to the fact that prophylaxis is still a relatively new idea, and that many people are unaccustomed to go to a physician for anything but the relicf of pain or actual illness. ical

tee itself said, "the actual

measure because of the multiplicity of factors involved." services in reducing illness There is a constant increase in the use of prophylactic measures, and physicians undoubtedly receive more training in the use of such measures, yet for a long time to come eurative medicine will be by far the major part of medical practice outside of mass public health measures.

Many general hygicnic measures for prevention are as dependent upon economic improvement as upon the application of prophylactic measures by physicians, and the report ignores an essential factor when it dissociates the problems of health, particularly in reference to the prevention of disease, from general economic conditions. The Committee acknowledges the inadequacy of pres-

ent medical income, and acknowledges that the provision for adequate compensation to physicians is a major es-sential of a satisfactory medical service. It also states as an essential that no plan is economically sound which does not safeguard quality. Nevertheless, the insurance plan which it sponsors makes it impossible to safeguard quality or to assure an adequate compensation for the physician unless the costs of such insurance are made so high as to defeat the primary purpose of reducing the costs of medical care,

The so-called "costs of medical care" is but one small aspect of a large sociologic problem. Sickness insurance in the last analysis means both direct and indirect tax-ation. There is no immediate prospect that our national income will materially increase. It is more than likely that for some time to come there will be a continuation in the fall of the national income—a tendency which has been noticeable for some time. Thus, the national incame.

in 1929 was....\$82,500,000,000, in 1930 was....71,000,000,000, in 1931 was....54,000,000,000, and in 1932 was....37,000,000,000 (estimated).

The tax rate per capita has shown a distinct tendency to increase. Thus, from \$19.39 in 1903 it rose to \$124 in 1932, and it cannot sustain an added burden.

The money required to finance an adequate system of insurance which would safeguard quality and assure the doctor suitable compensation would have to come from the State, and the costs of such a system would be so tremendous as to impose a terrific burden of taxation upon the nation. Since taxation must ultimately be borne by all the people, including the poor, this would be a transference and not a lessening of the costs of medical care.

Organization as such is not a thing to be worshipped. To call a place a medical center does not imply that it is a center of perfection. It is the character of the medical service that needs to be stressed, not the organization, nor its cost.

The conception that organized service through medical centers will insure a better grade of medical care is basically fallacions, since the quality of medical care depends ultimately on the quality of the practitioner. A good practitioner working alone holds out more promise of good medical care than a mediocre practitioner working in an elaborate center. The benefits which the Committee hopes to achieve through the creation of large centers are purely theoretical, while the losses that will accrue to the community through the destruction of the personal relationship between family and doctor are very real and very Important.

It has already been observed by those interested in medical education that too much stress is placed upon laboratory procedures and not enough attention paid to

clinical signs.

The concentration of medical practice in large centers would accentuate the tendency to diagnose by summarizing laboratory reports rather than by fine observation and sound elinical judgment. Furthermore, we are of the opinion that about 85 per cent of the diseases or affections with which people suffer are complaints that present no difficulties in diagnosis, but yield readily to treatment by the individual doctor in his private capacity. They are not susceptible nor amenable to mass treatment by health departments, centers or bureaus.

To place that portion of the public suffering from this 85 per cent group of cases upon the clinical resources of the country for elaborate "diagnostic workups" is to shoulder an expense that has no reasonable basis and its cost would be beyond the financial resources of the

community.

On the other hand, the present system of medical practice, for all its disadvantages, is flexible. It encourages the physician to be independent, courageous and resourceful in his thinking. It is hetter adapted to periods of depression like the present than an elaborate, expensive organization. Actually, even the indigent here receive a better type of service than the poorer class in Europe under compulsory health insurance.

From the time of the French revolution in 1792 to the recent sickness insurance in 1930 it has been manifestly apparent whenever compulsory health insurance has been put into practice that (1) the mortality has not decreased; (2) the average days' illness has increased from seven to seventeen days; (3) there has developed a huge amount of industrial neuroses; (4) malingering often reaches such extensive proportions as to eall forth governmental reactions; and (5) there has been no cor-

responding increase in preventive medicine.
In addition, your Committee contends that a fall in the death rate from 18.6 per thousand per year in 1900 to 12 per thousand per year in 1930 is an adequate answer to the critics of the present system of medical care.

FUNDAMENTAL PRINCIPLES

Your Committee believes that in considering the questions before it certain fundamentals must be comprehended. We believe first that sickness is primarily the problem of the individual; second, that the most desirable goal to attain in caring for the sick is a continuation and an improvement in the quality of medical care; third, that preventive medicine is also an individual problem, and not capable of solution by mass efforts of health departments; and fourth, in most cases the medical problem is a local one, differing with locality.

Thus the medical service in large cities differs from the problems presented in rural communities, and no plan of medical service can be devised applicable alike to a city like New York or rural communities in a densely populated State like New York, and communitics in sparsely populated areas like those of Nevada or the Dakotas.

Your Committee contends that no substantial evidence can be produced under which an idealistic system of medical service, irrespective of cost, could be devised medical service should be decided upon the principle of local needs and local autonomy.

I move the adoption of this section of the report.

Motion seconded and carried.

Dr. Rooney: Your Committee recommends in relution to paragraphs 10 and 11 of the Report of the Committee on Medical Economics that this Committee reiterate the statement of the policy of the House of Delegates of long standing in opposition to any form of practice by contract either actual or implied.

I move its adoption.

Motion seconded and carried.

Dr. Rooney: In relation to the matter contained in paragraphs 12 and 13 any conclusions formed from such inadequately small samples must be purely superficial and of no significance as to trueness or policy.

I move the adoption of this section of the report.

Motion seconded and carried.

Dr. Rooney: In order to expedite matters I suggest that a member of the House make the motion that as the Chairman of your committee make the motion for the adoption of these many propositions that the Speaker be empowered that they will be adopted, if there be no objection from the House, I think it will save much

This motion was made, seconded and carried.

Dr. Rooney: Your Committee recommends that the study of this subject be continued by the Committee on Medical Economics.

Your Committee disapproves of the policy presump-

tively outlined in paragraph 14 of the Report.

Your Committee recommends that the policy of conducting all arbitrations in New York City be disapproved and that our approval be given to the policy of conducting arbitrations in the counties in which the con-

In relation to the draft of the new medical section for inclusion in the law relating to Workmen's Compensation your committee has felt compelled to make many changes: (a) to elarify the meaning of various paragraphs; (b) to eliminate certain provision in the original draft; (c) to place more completely all power in rela-tion to the medical administration of the law in the hands of those best fitted to do justice to all concerned. that is, the organized medical profession; (d) to secure justice to the employee, the employer or carrier, and the State.
Your Reference Committee submits this amended

draft.

Subdivision 1: Eliminate the word "eligible" in the last sentence and substitute "legally qualified person."

Under subdivision 2: "Those eligible to render medical care"—(a) strike out under Article 48, Section 1251 of the Medical Law, and have the section read: person licensed and registered to practice medicine in the State of New York." Delete "provided." Delete sub-paragraphs b and c and a new paragraph d will then be b; paragraph e will be c, and f will become d. In old paragraph f delete "must" in the second line and in the second sentence, and substitute "shall" in both instances. Paragraph g becomes e and should read: "Any person, firm, or corporation, who shall solicit by himself or for another the professional treatment, examination, or care of an injured employee, or who shall make it a business to solicit in person or by circular or placards the employment of a physician or physicians, in connection with any claim under this chapter shall be guilty of a misdemeanor."

Subdivision 3: Remuneration: The Reference Committee recommends that the word "remuneration" be changed throughout this subdivision to "payment" with the following other substitutions by section.

(a) Payment for medical service shall consist of a fair and adequate return to persons qualified to render medical care under this act and such charges shall be based on the social and economic status of the individual and shall be the same as the charges that pervail in the same community for similar treatment of injured persons of a like standard of living not covered by this act.

Subdivision B: Under subdivision C: All payments for such services shall be made within 30 days by employer or carrier or shall be protested to the Labor Department within 30 days of the date on which bill for such service was mailed.

Subdivision D: Any person participating in the act of dividing, transferring, assigning, subordinating, rebating, splitting, or refunding, or who by any subterfuge is a party to such dividing, transferring, assigning, subordinating, rebating, splitting, or refunding of a fee for medical care under this act shall be guilty of a misdemeanor, except that this rule shall not prohibit the payment of salarics by a qualified physician to others rendering medical care under his supervision as provided

in Subdivision 2, Paragraph D of this section.
Subdivision 4: (a) We recommend that this Section be amended to read: Said Commissioner or referee shall approve or direct the appeal of such determination; he shall not alter, modify, or change such determination,

(b) In the end result after accident or accidents the following shall be used as a general guide for the determination of the degree of disability:

1. Function, or capacity to perform.

2. Union, or state of repair of parts injured.

3. Contour, or external appearance, including presence or absence of facial or other disfigurements.

Subdivision C: Thereafter delete to subdivision C: In the second line change "and" to "or." In the fourth line remove parentheses around "or carrier." The second sentence will read as follows: "The determination in such appeals shall be rendered by the Medical Advisory and Appeal Board of three physicians appointed by the Commissioner from a list of not less than twelve members nominated by the County Medical Society in the County where the member resides or elects to be heard."

In line 15, strike out "this" and substitute "these." Remove "or these" in parentheses, and add "s" to Board. Remove words "or Boards" in parentheses and in line 17 substitute "and" for "or." Substitute the following for the last sentence: "Whenever a County Medical Society fails to nominate a Medical Advisory and Appeal Board in accordance with this section of the law within two weeks from the time of the mailing of the request for such payment the Medical Society of the State of New York shall nominate such a Board in accordance with the provisions of this section."

Subdivision D: Substitute this phraseology: Industrial Board or an Appeal Board may avail themselves of the written opinion of an expert upon the examination of a claimant with the approval of the Commissioner of Labor who shall also direct the award of compensation for such service, the payment to be that usual for the Community in which the appeal is heard.

Sub-paragraph E: Substitute this phraseology: Whenever a case is reopened the review and re-adjudication of the determination of the degree of disability may be obtained upon order of the Commissioner of Labor after application by the referee who rendered the original decision or by employee or by employer. This review or re-adjudication shall follow the course herein prescribed for the primary determination of disability.

Delete matter in parentheses at the end of this sub-

Subdivision 5: Delete parentheses and question marks. Subdivision 6: Substitute the following: Arbitration bills for market and of bills for medical care. Employer or carrier and physician shall arbitrate all contested bills for medical care. Such contested claims shall be billed by the arbitration committee consisting of two members of the Medical Society of the County in which the claimant physician resides, appointed by the President thereof; two physicians also members of the Medical Society of the State of New York appointed by the employer nr carrier and examining physician in the employ of the Labor Department designated by the Commissioner of Labor, who shall be Chairman of such Arbitration Com mittee and who shall be entitled to vote only in the event nf an equal division in the Arbitration Committee decision of the Board of Arbitration shall be final

Subdivision 8 At the circl of the paragraph include to following 'No such waiver shall prevent however the following an individual from claiming a compensation not attrib utable to an aggravation or reactivation of the impair

ment wanted against

In the second paragraph delete Article 48 Section 1251 of the Medical I aw and substitute 'm' for 'of

Subdivision 10 On the second line delete within Delete parentheses around 'not cirbons Delete parentheses around "or carrier" Delete paren

Subdivision II In the sixth line delete first or" and Subdivision 1 In the ninth line, following the word 'disability add 'is provided under Subdivision 4 Paragraph A of this section"

At the end of this section, Subdivision II, add 'of

this section

Subdivision I2 In the third line after the word 'alue include and in' In the fourth line remove parentheses around or earriers' In the fifth line after the word corrected' add without serious risk to life In the eleventh line delete first 'or' Remove paren theses around 'or carrier' In the sixteenth line after paragraph C, add 'of this section' In the nuneteenth line delete parentheses around 'or earrier'

Subdivision 13 Substitute this pliraseology The Committee on Discipline shall be appointed by the Com This committee shall consist of eight quali-mans. The Commissioner shall appoint the fied physicians members of this committee by selection from a list of at least eight members from each District Branch of the Medical Society of the State of New York submitted to the Commissioner by the President of such District Branch one of each eight thus chosen to be appointed to membership on this Board. The function of this committee shall be to receive charges conduct hearings and make recommendations to the proper authorities in any case of formal complaint, and filing of charges against qualified physicians after due hearing by such Board of all charges purporting to show professional or other misconduct in connection with medical service rendered under the Workmen's Compensation Law, ex cept that the original appointments shall be so made that four members shall serve one year and four members two years Thereafter each appointment shall be for two years Any physician found guilty of neglect mis conduct deceit or gross unfitness in the treatment of injured workmen in the province of this law shall be suspended from participation and privileges of rendering medical care under this law by the Commissioner of Labor upon recommendation of the Committee on Disci pline The Commissioner of Labor upon receiving notice from the Committee on Discipline of their finding a physician guilty of neglect misconduct deceit, or gross unfitness as above stated shall notify the Commissioner of Education of the State of New York of such find ings which report the Commissioner of Education will place before the Board of Regents for their opinion in proceedings if the charges come within the province of the Public Health Law relating to the suspension or revocation of license to practice medicine

That concludes the report of the draft of the law and I wish to say to the House that this is merely a statement or a draft embodying the desires of the Society to be in turn submitted to Governor Lehman's Commit tee appointed for the purpose of correcting the abuses in the Workmen's Compensation Law I move the adop tion of the Reference Committee's recommendation

The Vice Speaker I have a note in reference
Committee B referred to me in this matter 7

Charman of the Reference Committee 'B is privileged to report to the floor because the report of his section

was postponed to this particular time

Dr Jennings Resorted that the House of Delegates be authorized to instruct the President to appoint a com untlee for the turpose of studying the professional aspects of the Workmen's Compensation and to make recommendations to the Precutive Committee on the de strainlity and method of formulating a plan whereby the State Society may set up a basic organization through the constituent local societies for the administration of the professional aspects of the Workmen's Compensation

The Committee recommends that this resolution be discussed in combination with the recommendation of the Reference Committee on I conomics on this subject

Dr Jennings I mine its adoption

I second the idoption of Dr Jennings Dr Roones

motion The motion was earried

Now Mr Speaker I move the adop Dr Roones tim of the draft submitted by your Reference Commuttee The Vice Speaker There being no objection it stands adopted

Dr Rooney Paragraph 19 Your Reference Com mittee recommends that the House of Delegates record its disapproval of any extension of the number or nature nf compensable diseases beyond those already enumer

ated in detail section 3 subdivision 2 of the present law. We recommend that the Medical Society of the State nf New York recognize the need of a new chapter in the Public Welfare law which shall specify the prin eiples upon which medical care shall be given to the indigent and provide for reasonable compensation to the physicians rendering services. We recommend that the said medical chapter should contain the provision that the uningent persons thus served should have the privilege of choosing the physician to whom they should go and that the principle of hiring one or two lowest bidders to do all the medical work in the County is not good public policy

We recommend that the Medical Society of the State of New York instruct the Committees on Public Health Public Relations and Feonomies to join in the drafting of a desirable chapter as suggested ut recommendation paragraph 27 and such other amendments as would seem best for the welfare of the people of the State of New York including New York City

We recommend that the Geib Vaughan Detroit Plan of Public Health Work be cordully and completely approved by the Medical Society of the State of New York and that the State Society initiate active efforts to intro iluce this principle of participat - of the medical prince fession in Public Health work hoth preventive and curative throughout the State of New York

We recommend that the President appoint a commit tee representing the several branches of medical science and practice to study the field of Preventive Medicine and in association with the several standing committees to prepare and present authoritative information and recommendations in a coordinated report calculated to msure the development of this work in accordance with sound principles of medical organization and practice

The Vice Speaker Are there any objections to these recommendations? If not they are approved

Dr Rooney Your committee recommends paragraph 40 We recommend the fourth sentence should read as follows. These promulgated rules and regulations have the same force and effect as law'

Paragraph 42 Your Committee recommends that the constitution powers and potentialities of the Public Health Counsel be referred to the joint consideration of the Committees on Public Health Public Relations and Economics with legal counsel for report at the next Annual Meeting of the house

This committee also recommends this joint committee consider the importance that at least two of the three Delegates to express its appreciation of its efficient activity.

The following supplementary report of the Committee on Legislation has also been referred to us.

SUPPLEMENTARY REPORT

The Legislature is still in session and unless the Beer Bill is disposed of soon, may remain in session indefinitely. However, we have been informed that the Anti-Vivisection and Osteopathy Bills have been killed in the Assembly Committee.

A Chiropractic bill was introduced by Senator Feld of New York. May I urge that every delegate send a letter of protest to his Senator and to the members of

the Senate Committee on Education.

In our report to the House of Delegates last year we recommended that the legislative policy of our Society be changed from passive resistance to aggressive action. Our experience with the Crawford and Evans bills has convinced us that our recommendation was wise and that the members of our Society are willing and ready to support such leadership. Never in the experience of the Committee has there been such enthusiastic and spontaneous response from the members of the Medical Profession as in the support of the Crawford-Evans bills. At the hearing on these bills last Thursday representatives of nearly every medical, dental and pharmaceutical society in greater New York appeared in favor of the bill. The Senate Committee were favorably impressed by our organization and I expect the bills to come out on the Senate floor.

For years the dispensary abuse has received very little attention from the directorate and management of the hospitals. Efforts on the part of the Medical Association to meet these gentlemen in order to control these abuses have been repeatedly refused; nay, we were even told to mind our own business. Now, suddenly the management of the hospitals' organizations realize that organized medicine is alive and they became anxious to At the above-mentioned hearing the hospital representatives conceded that the medical profession was right and they suggested that we meet them at the Round Table to straighten out our differences and not

push the Crawford Bill.

Year after year the medical profession has to fight for the public in opposition to Anti-Vivisection, Chiropractic and other quack bills. So far, through the watchfulness and personal efforts of our executive officer, Dr. Joseph S. Lawrence, we have been able to protect the public from vicious legislation. We may not always be so fortunate. Let me again urge the House of Delegates to appoint a special committee whose duty it shall be to see that the leading citizens in every community be organized to assist the medical profession in protecting the public against these repeated attacks on public health and welfare.

Let me urge again that the various County Societies watch the work of the Legislators and that, irrespective of their party affiliations, Legislators who have repeatedly shown themselves to be antagonistic to the interests of the medical profession, be opposed for renomination and if nominated, each County Society actively fight their election.

The Reference Committee moves the adoption of these

Reports.

Dr. Rooney: I would like to rise to a question of information before the adoption of the report of this Reference Committee. Does it include and recommend to the House of Delegates the proposition of the Chairman of the Committee on Legislation for the appointment of another committee, to be added to the present ones?

The Vice-Speaker: I think it does.

Dr. Rooney: That was my impression. I, therefore, move a substitute to the motion of the Chairman of the Reference Committee that the House of Delegates approve the Report of the Reference Committee except the portion referring to the appointment of another committee. I move that that be deleted.

The Vice-Speaker: Dr. Ludlum accepts the substitution, therefore it is not necessary to vote upon it, and the motion now is that of the Chairman of the Reference Committee for the adoption of the report with the deletion of that portion that refers to a special committee.

Motion seconded and carried.

The Vice-Speaker: Is there any further business?

67. RADIOLOGICAL SECTION

(Sections 11 and 47)

Dr. Jennings: WHEREAS it would be to the benefit of the best interests of the Medical Society of the State of New York,

Whereas it would be to the best interests of the New York State Journal of Medicine,

WHEREAS it would be for the good of the Medical and Surgical Profession,

WHEREAS it would be favorable to the general education and mutual benefit of the roentgenologists of this

Society and State, WHEREAS this would reflect also to the advantage of patients and the public generally,

WHEREAS the temporary session granted has proved

a definite success,

WHEREAS Roentgenology has become a very impor-

tant integral part of our profession, and
WHEREAS the five individual x-ray societies, namely,
the New York City, the Brooklyn, the Central New
York, the Rochester and the Buffalo groups, desire this section.

THEREFORE, BE IT ASKED AND RESOLVED, that the House of Delegates of the Medical Society of the State of New York establish a section known as the Radiological Section of the Medical Society of the State of New York.

The Committee recommends the adoption of this report.

Motion seconded and carried.

68. REPORT OF THE REFERENCE COMMITTEE ON THE REPORT OF THE SECRETARY, COUNCIL, AND COUNCILORS

(Journal, March 1, 1933, pages 262, 265, 300)

Dr. Krieger: Your Committee notes with pleasure the evidence of Dr. Dougherty's recovery from his recent illness as indicated by his enlightening report. We join Dr. Dougherty in his tribute to Dr. John A. Card and emphasize the great loss that this House of Delegates has sustained in his passing.

It is interesting to note that despite this time of financial stress, so many county societies have increased their annual dues. This is testimony of the strength of organized medicine in New York State.

Your Committee feels justified in calling particular attention to the additional duties imposed upon Dr. Peter Irving by the recent illness of the Secretary, and the efficient manner in which he eonducted the affairs of the Secretary's office in Dr. Dougherty's absence.

Your Committee calls attention to the numerous activities of the Executive Committee, the several actions taken for the benefit of the membership of the State Society, and the wise selection of the Committee personnel made

by the President and indorsed by the Committee.

Your Committee notes the following paragraph in the Report of the Council: "Some doubt having been expressed as to the resolution passed by the last House of Delegates against the distribution of form the Legal of Delegates concerning the division of fees, the Legal Counsel's advice was sought as to whether this might not be in conflict with the Principles of Professional Conduct—The Counsel's opinion was that it constituted an extremely depression and the constituted and extremely depression and the constituted are extremely depression. an extremely dangerous precedent and was repugnant to and in conflict with the meaning and purposes of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and purpose of Section 32 of the Delivite meaning and the Section 32 of the Delivite meani tion 32 of the Principles of Professional Conduct.

The Council's Report does not disclose what the attitude of the Executive Committee has been since the

Counsel's opinion was rendered.

Your Committee has analyzed carefully the "Rules Governing Malpractice Defense and Group Insurance," approved by the Executive Committee, together with the amendments handed to your Committee under this date. Your Committee is of the opinion that the provisions of these rules will operate to the advantage of the members of the Medical Society of the State of New York as a whole

Your Committee has reviewed the several reports of the various Councilors and commends the District Branches for their activities during the past year.

Your Reference Committee on the Reports of the Secretary, Council and Councilors make the following recommendations:

1. That the Counsel be requested to state his opinion regarding the resolution passed by the last House of

Delegates concerning the division of fees.

2. That the rules governing malpractice defense and group insurance be adopted as printed and amended.

3. That the Committee to Prepare a History of Medicine in the State of New York and the Committee to Consult with the Saratoga Springs Commission in its effort to develop the mineral resources of Saratoga Springs be continued.

I move the adoption of the report.

Motion seconded and carried.

On motion duly seconded and carried the meeting adjourned until Tuesday, April 4th, at 9:00 A.M.

ADJOURNED SESSION OF THE HOUSE OF DELEGATES Tuesday, April 4th, 1933

The meeting was called to order by the Vice-Speaker at 9:00 A.M.

69. ROLL CALL

The Vice-Speaker: The first order of business will

be the roll call.

The Assistant Secretary called the roll and the following delegates responded;

lowing delegates responded:
Frederie C. Conway, William P. Howard, Edgar A. Vander Veer, Lyman C. Lewis, J. Lewis Amster, Harry Aranow, Edward R. Cunniffe, Louis A. Friedman, Vincent S. Hayward, William Klein, Moses H. Krakow, Arthur B. Sullivan, Blinn A. Buell, Perry H. Shaw, Joseph P. Garen, Harry S. Bull, Edgar Bieber, DeForest W. Buckmaster, Reve B. Howland, Earl W. Wilcox, Anton S. Schneider, Charles J. Kelley, Robert Brittain, C. Knight Deyo, William A. Krieger, Aaron Sobel, George R. Critchlow, Robert E. De Ceu, James H. Donnelly, John T. Donovan, Mary J. Kazmierczak, Thurber Le Win, Edward J. Lyons, Herbert A. Smith, Charles C. Trembley, Sylvester C. Clemans, Peter J. Di Natale, Alton B. Daley, O. Houghton Love, Murray M. Gardner, Robert F. Barber, John L. Bauer, Bernard B. Berkonder, St. Peter J. Din Natale, Alton B. Daley, O. Houghton Love, Murray M. Gardner, Robert F. Barber, John L. Bauer, Bernard B. Berkonder, St. Peter J. Din L. Bauer, Bernard B. Berkonder, St. Peter J. Din L. Bauer, Bernard B. Berkonder, St. Peter J. Din L. Bauer, Bernard B. Berkonder, L. Peter J. Din L. Bauer, Bernard B. Berkonder, P. Barber, John L. Bauer, Bernard B. Berkonder, L. Peter J. Din L. Bauer, Bernard B. Berkonder, P. Leven, P. Leven C. Tremoley, Sylvester C. Clemans, Peter J. Di Natare, Alton B. Daley, O. Houghton Love, Murray M. Gardner, Robert F. Barber, John L. Bauer, Bernard B. Berkowitz, Siegfried Block, Thomas M. Brennan, E. Jefferson Browder, Frederic E. Elliott, Herbert C. Fett, Gordon Gibson, Alec N. Thomson, John E. Jennings, Henry Kresky, Walter D. Ludlum, Thomas A. McGoldrick, John J. Masterson, Harvey B. Matthews, Benjamin Rabbiner, Joseph Raphael, Hyman L. Ratnoff, Irving Gray, Alfred E. Shipley, James Steele, Luther F. Warren, F. Edward Jones, William T. Shanahan, Byron S. West, Clarence V. Costello, William A. MacVay, Willard H., Veeder, Edward T. Wentworth, Floyd S. Winslow, William H. Seward Benjamin R. Allison, James W. Bulmer, Emily D. Barringer, Milton A. Bridges, Edward M., Colie, Jr., Walter T. Dannreuther, Adolph G. De Sanctis, John Douglas, Ten Eyck Elmendorf, Julius Ferber. B. Wallace Hamilton, David J. Kaliski, Samuel M., Kaufman, Frederick C. Keller, George W. Kosnak, William M. Fisher, James E. Sadlier, Harry R. Trick, James N.
Vander Veer, William H. Ross, William D. Johnson.
Ex-Sections: Educated Maries Presidents

Ex-Secretary, Edward Livingston Hunt.

0. Election of Officers

The Vice-Speaker: There being a quorum present

the next order of business is the election of Officers.

The Assistant Secretary announced the tellers: Fredrick Assissant Secretary announced the tellers! Frederick J. Schnell, Chairman, Edward W. Weber, John T. Donovan, Edgar Bieber, Clarence V. Costello, John L. Bauer, David J. Kaliski, Albert G. Swift, William W. Street, Allen W. Holmes, Ralph Sheldon, James R. Reuling, Jr., Joseph P. Garen, Dan Meilen. For the election, see Section 75.

71. PRESIDENT'S INAUGURAL ADDRESS

Dr. Frederick H. Flaherty, President-cleet, delivered an address on "The Control of Medical Activities by the Medical Profession." This address was printed in the Journal of April 15, 1933, page 497.

72. PRINCIPLES OF PROFESSIONAL CONDUCT (Sections 19 and 54)

Dr. Sobel, Chairman, Reference Committee on New Business A, presented the following amendment to Section 32 of the Principles of Professional Conduct: Section 32. Physicians shall not give, solicit, or receive, nor shall they offer to give, solicit, or receive any gift, gratuity, commission, or bonus in consideration of or in return for the referring, recommending or procurng of any patient for medical, surgical or other treatment

Physicians shall not directly or by any subterfuge, participate in, or be a party to, the act of the division, transference, assignment, subordination, rebating, splitting or refunding of any fee for medical, surgical

or other treatment.

The provisions of this section shall apply with equal force to the referring, recommending, or procuring by a physician of any person, specimen or material for diagnostic or other study or work.

Nothing in this section, however, shall prohibit the payment of salaries by a qualified physician to other duly qualified persons rendering medical care under his supervision.

しっな変化

I move its adoption. Motion seconded and carried.

73. REVISED CONSTITUTION . (Section 49)

Dr. Sobel: WHEREAS times change and we change with them, and

WHEREAS certain modifications of organization become at times desirable,

THEREFORE BE IT RESOLVED, that the Speaker of this House of Delegates of the Medical Society of the State of New York is empowered and directed to appoint from this House a committee consisting of one member from each District Branch and a chairman to prepare a Revised Constitution and present such revision to the next meeting of the House of Delegates.

I move its adoption.

A vote was taken and the motion was lost.

74. MEMORIAL TO JOHN ALLING CARD, M.D.

The Secretary: The next order of business is the memorial to Dr. Card prepared by Dr. Sadlier at the request of the Executive Committee. I move that it be spread on the Minutes of the House.

I move that the memorial be read as we can well afford a few minutes to hear the tribute to one whom

we all loved and revered.

Motion seconded and carried.

Dr. Rooney: In the carly morning of June 28, 1932, as the sun was rising out of the east, surrounded by some of the friends with whom he had worked for many years, our Speaker of the House of Delegates passed to his reward in the great world beyond. His earthly career was ended but the influence of his life will carry on and on throughout the years to come, and the world will be the better for his having lived and been a part of it.

John Alling Card was born in Poughkeepsie, N. Y., May 20, 1877, the eldest son of the late Silas E. and

Eva Belle Alling Card.

After graduating from the Poughkeepsie High School at the age of 16 he entered Columbia University. He completed his medical course in the New York University Medical College in 1898, before he had reached the

age of 21 years.

His first experience in the work of his profession came to him as an interne on Blackwell's Island and the Bellevue Hospital, following which he returned to Poughkeepsie as a general practitioner. He served as physician for the City of Poughkeepsie for several years. Within a few years Dr. Card took up Pediatrics, doing bedside work with the late Dr. Holt at the Babies Hospital in New York for eight years.

He was elected Coroner of the County of Dutchess November, 1917, beginning his duties January, 1918, and continuing in this office, several times receiving the largest number of votes given to any candidate in the county, until June 1st, 1932, when it was abolished and a Medical Examiner was appointed. This position was tendered Dr. Card, and accepted by him and he began his duties June 1, 1932.

His hospital affiliations were, attending Pediatrician on the Staff of Vassar Brothers Hospital and consultant in this specialty on the staffs of St. Francis. Bowne Memorial Hospitals, Poughkeepsic, Dutchess Hospital at Rhinebeck. and Northern

Dr. Card organized the Child Welfare of the City of Poughkeepsie during 1907 and gave of his time liberally in developing Well Baby Clinics. For many years he has been in charge of the Well Baby Clinic sponsored by Mrs. Vincent Astor at Rhinebeck.

When the Poughkeepsie Board of Health developed Department of Child Hygiene he was made its direcand held that position until the time of his death.

was an outstanding man in the Dutchess-Putnam Society and has served as Secretary, President, of the Committee on Legislation and Chair-1e [ittee on Public Relations. Seldom was

he absent from a niceting. His leadership was recognized by all members of the Society. He was first secretary and then later president of the Poughkeepsie Academy of Medicine, which some years ago was merged with the Dutchess-Putnam Medical Society.

In 1925 he was President of the First District Branch of the Medical Society of the State of New York.

He served continuously as member of the House of Delegates of the Medical Society of the State of New York from the Dutchess-Putnam Medical Society for the last 16 years. When President of the First District Branch he was appointed to the Executive Committee of the Medical Society of the State of New York (1925) and has been continuously reappointed year by year and

was serving in that capacity at the time of his death.

He was elected Vice-Speaker of the House of Delegates of the Medical Society of the State of New York in 1926 serving two years, when, by reason of the Speaker, Dr. E. Eliot Harris, being incapacitated by illness, Dr. Card was elected Speaker of the House of Delegates at its annual meeting in Albany, May, 1928, and has been re-elected annually to that office. He served continuously as a Delegate to the American Medical Association since 1926.

As Chairman of the Committee on Group Insurance of the Medical Society of the State of New York, Dr. Card rendered a very faithful and signal service to the medical profession of this State. He met with each of the eight District Branch Societies at their annual meetings. ings and very forcibly warned them against the dangers of malpractice and the necessity of protection.

Dr. Card's interest in medicine is well exemplified in his faithful attendance and active participation in the work of the County Society of the First District Branch and the Medical Society of the State of New York From the onset of his medical career he assumed duties and responsibilities so naturally that he was advanced from one position of honor and trust to another of greater proportions in the County Medical Society which in turn was followed by election to presidency of the First District Branch. This position placed him in the Council of the Parent Body and from thence he was appointed to the Executive Committee of the State Medical Society serving continuously for seven years without once missing a meeting. This continuation of office was made possible by his election as Vice-Speaker and later, 1928, Speaker of the House of Delegates, a position he held at the time of his death. For six years he served the State Medical Society as a Delegate to the American Medical Association. From all of this you will be reminded of that verse,

> "The heights by great men reached and kept Were not attained by sudden flight, But they, while their companions slept Were toiling upward in the night.'

Undoubtedly his most distinguished medical servic was rendered as Speaker of the House of Delegates where he was uniformly fair and impartial. The following, taken from The New York Medical Week, gives proper recognition of his service:

"In his duties as Speaker of the House of Delegates of the State Society, which position he held for many years, he had ample opportunity to display the tact, intelligence and ability characteristic of him to handle difficult situa-tions. His infinite patience, his kindliness, his tolerant good nature lessened the tension in many a heated debate and made his decisions acceptable to opposing factions without an aftermath of rancor.

Dr. Card was a man of strong convictions, good judgment and a personality which was respected by all. Just and impartial in his decisions he naturally became a leader in the many phases of his active life and especially so in his medical associations.

He died at his post of duty at the hour when medi-cine requires just such strong minds. His death means a loss to this Society which seems almost irreparable.

Dr. Rooney: I move, Mr. Speaker, that this Society adopt this expression of appreciation of the services of our former Speaker and that it be spread upon the minutes of the Society and a copy thereof be sent to any surviving relatives.

The motion was seconded and earried.

75. Election of Officers (Section 70)

The lollowing officers were nominated and elected: President-elect, Arthur J. Bedell; First Vice-president, Ralph R. Fitch; Second Vice-president, Charles D. Kline; Secretary, Daniel S. Dougherty; Assistant Secretary, Peter Irving; Treasurer, Frederic E. Sondern; Assistant Treasurer, James Pedersen; Trustee, George W. Cottis; Speaker, Samuel J. Kopetzky; Vice-Speaker, Floyd S. Winslow; Chairman of Committee on Egislation, Harry Aranow; Chairman of Committee on Legislation, Harry Aranow; Chairman of Committee on Public Health and Medical Education, Thomas P. Farmer; Chairman, Committee on Medical Econom-The following officers were nominated and elected:

ies, Frederie E. Elliott; Chairman of Committee on Public Relations, James E. Sadlier. The following were elected Delegates to the Ameri-

can Medical Association for 1934-35:

Drs. Daniel S. Dougherty, Nathan B. Van Etten, William H. Ross, George A. Leitner, Orrin S. Wightman, George M. Fisher, George W. Kosmak; Thomas P. Farmer was elected Delegate for 1933-34 to fill the unexpired term of Dr. John A. Card.

The following were elected Alternates to the Ameri-

can Medical Association:

Drs. Louis A. Van Kleeck, James N. Vander Veer, Luther F. Warren, Joseph F. O'Gorman, J. Richard Kevin, Carl Boettiger, Frank M. Sulzman.

Moved, seconded and carried that the election of the Chairman of the Committee on Arrangements be referred

to the Council.

76. ADJOURNMENT

Dr. Rooney moved that the House of Delegates adjourn sine die.

Motion secunded and earried.

GEORGE W. COTTIS, Vice-Speaker. DANIEL S. DOUGHERTY, Secretary.

NEWS NOTES

LEGISLATION, SPECIAL BULLETIN, APRIL 17, 1933

The following bills in which we have been interested this year have been signed by the Governor:

Senate Int. No. 993—Twomey, amending the Education Law relative to payment of certain monies into state treasury, so as to postpone until July 1, 1935, time when act shall take effect. Chapter No. 153 of the Laws of 1933.

Senate Int. No. 1590—Buckley, Tax Law, imposing an excise tax of 31/3c per gallon on beer, and appropriating \$50,000 for temperance education. Chapter No. 142 of the Laws of 1933.

Senate Int. No. 1983—Dunnigan, enacting Alcoholic Beverage Control Law. Chapter No. 180 of the Laws of 1933.

BILLS IN HANDS OF GOVERNOR

Senate Int. No. 621—Quinn, amending Criminal Code, by providing for employment of experts not exceeding two, in a criminal case where affirmative presentation of evidence is incumbent on defendant and prosecution has not indicated any number of experts to be employed.

Senate Int. No. 1043-Esquirol, Health Law,

enacting a uniform Narcotic Drug Law.

Senate Int. No. 1556—Esquirol, amending

Mental Hygiene Law generally.

Senate Int. No. 1791-Blumberg, Penal Law, making it misdemeanor for applicant for public welfare relief or person receiving such relief for another person, to make a fraudulent or false representation.

Senate Int. No. 1510-Esquirol, Workmen's

Compensation Law, by placing in excepted employments inmates of, and other recipients of charitable aid from, a religious or charitable institution, who perform work in or for the institution in return for aid conferred.

Assembly Int. No. 782-Robinson, Criminal Code, relative to proceedings when a person in confinement appears to be insane or a mental de-

fective.

Assembly Int. No. 692—Horn, County Law, by providing no person, not residing in Rockland County for at least three years, shall be admitted as a patient to Summit Park Sanatorium at Pomona, as a county charge.

Assembly Int. No. 705-Austin, Public Health Law, by providing rules or regulations for protection from contamination of potable water supplies shall be published at least once each week for two instead of six consecutive weeks.

Assembly Int. No. 772—Doyle, Penal Law, regulating sale and manufacture of bichloride of mercury and compounds thereof and to prevent

accidental poisoning.

Assembly Int. No. 2439—Esmond, creating the Saratoga Springs Authority to construct on lands of Saratoga Springs Reservation, a cure devoted to use of mineral waters for public health purposes, to lease such lands from the state and construct incidental facilities, and to issue bonds.

All other bills in which we had an interest were defeated.

HARRY ARANOW, Chairman.

THE AMERICAN MEDICAL ASSOCIATION MEETING

The annual meeting of the American Medical Association which will open in Milwaukee at 10:00 A.M. Monday, June 12th, 1933, will undoubtedly attract many members of the Medical Society of the State of New York.

Milwaukee has ample hotel facilities for the adequate accommodation of all visiting delegates. The railroads are more liberal in their rates this year than ever before. Fare and one-third for the round-trip has been authorized. The plan is to purchase a one-way ticket from your home station to Milwaukee. When you purchase your ticket, secure from the Ticket Agent a certificate which should be validated by the special agent of the carriers, who will be in attendance at the

meeting. The ticket, when properly validated, should be presented to Ticket Agent, who will issue a return ticket at one-third of the going fare This return ticket has the liberal provision of permitting a stop-over at Chicago to visit the "Century of Progress" Exposition.

On June 1, 1933, in the city of Chicago, the curtain will rise on Chicago's Great World's Fair, one of the most enthralling dramas ever produced by man. It is a masterful, colorful presentation of human achievement during the past century

and will appeal to all physicians.

Either special cars, or if numbers justify, a special train, will be operated over the New York Central and Chicago & North Western Railroads to Milwankee, leaving Grand Central Terminal 7:45 P.M. Eastern Standard Time Saturday, June 10, arriving Milwaukee about 7:00 P.M. the following day. Reservations may be secured on the above or any other New York Central train by addressing Mr. J. S. McAndrew, Room 1216, 466 Lexington Avenue, New York CityTelephone Murray Hill 2-8000, Extension 671. Your cooperation is earnestly requested in order to make possible the convenience of through service to your Convention City.

DANIEL S. DOUGHERTY, Chairman of the Special Committee on Transportation.

ONEIDA COUNTY

The quarterly meeting of the Oncida County Medical Society was held in the Hotel Utiea on Tuesday, April 10, 1933. The society plans to give Mothers' Day, May 14, a new meaning, for it voted to cooperate with community clubs and health organizations to educate the people on the subject of Maternal Mortality. The program for Mothers' Day in the past has been centered on prenatal care. This year, with the cooperation of the County Medical Society, the need of hospital care at the time of delivery will be emphasized.

Dr. T. H. Farrell, Chairman of the Committee on Public Relations, reported on the relation of the Temporary Emergency Relief Administration to the rural committees, and said that forty per cent of the costs of medical care of the indigent would be refunded by the State.

Dr. Farrell also reported on the progress of the campaign for the early care of cases of tuberculosis, which is being conducted under the leadership of Dr. W. C. Jensen, Superintendent of The County Sanatorium, Dr. S. A. Mahady, School Medical Examiner, and Dr. H. J. Ball, District State Health Officer.

Dr. J. S. Lawrence, Executive Officer of the State Medical Society, reviewed the action of the

Legislature on medical bills,

Dr. John F. Kelly of Utica read a paper on intestinal obstruction.

Dr. F. M. Miller, Jr., read a paper on the transposition of the viscera.

Dr. G. A. Holden discussed the relation of the coroner to the district attorney.

Dr. G. F. Jones, Utica, and Howard Beach. Sherrill, were elected to membership.

The next meeting will be the annual outing and will be held on July eleventh.

W. HALE, JR., Secretary.

DUTCHESS-PUTNAM

A regular meeting of the Dutchess-Putnam Medical Society was held Wednesday, April 12, 1933, at the Chimney Corner, Poughkeepsie, N. Y. The meeting was called to order by the President, Dr. S. E. Appel at 9:00 p.m.

The minutes of the February and March meetings were read and approved.

Drs. C. W. Layne, Beacon, N. Y., and L. W. Stoller, Red Hook, N. Y., were elected to membership.

It was regularly voted that matters concerning mental hygicne work be left to the Dutchess County Psychiatric Society.

It was regularly voted that the Economics Committee headed by Dr. James T. Harrington investigate Workmen's Compensation, arbitration, and outline a plan for the Dutchess-Putnam Medical Society to be presented at the next meeting.

A letter from County Welfare Commissioner Cox concerning rules and relations governing medical care to Home Relief patients was ordered submitted to Commissioner Burnett by the Public Relations Committee.

Program

Professor Howard J. Howson, Vassar College, "What Freud Has Accomplished."

Discussion by: Dr. Richard H. Hutchings, Jr., Harlem Valley State Hospital, Wingdale, Dutchess County; and Dr. James P. Kelleher, Hudson River State Hospital, Poughkeepsie, N. Y.

Meeting adjourned at 10:45 p.m. for refresh-

Present: Drs. Voorhees, Peekham, Harrington, Thomson, Cadwell, Gosse, Wilson, Cranc, Howson, Kelleher, Krieger, Deyo, Appel, Carpenter, Hedgecock, Andrews, Borst, C. E. Lane, Marks, Davison, Cavanaugh, Rivenburgh, Conger, Rogers, Sobel, Leonidoff, Rosenberg, Smith, Lander Hamilton, Conger, Tonger, Palithic Stoller, Harrington, Stone, Languer, Baldwin, White, Breed, Keating, Jennings, Storrs, Hutchings, McGrath, G. E. Lane, C. A. Crispell, Simon, Price, Cotter, Toomey, Bacile, Harin.

II. P. CARPENTER, Secretary.

GRADUATE COURSES

The Committee on Public Health and Medical Education desires to direct attention to suggested plans for the extension of graduate education among the members of the State Medical Society. Discussion of this subject appears as part of the Committee's annual report to the House of Delegates which is published in the March first issue of the New York State Journal of Medicine, page 277.

As the first step to the inauguration of one week graduate courses in New York City, through the offer of the Administrative Board of Postgraduate Studies in Medicine of Columbia University, it is necessary to know how much demand there is for this type of instruction. Unless at

least twenty physicians throughout the state register for a definite course it is doubtful whether such courses could be organized. Consequently any physician interested in registering for such a course should immediately inform Dr. Thomas P. Farmer, 608 East Genesee Street, Syracuse, New York, Chairman of the Committee on Public Health and Medical Education of the New York State Medical Society, or the secretary of his local county society regarding his desire to take such a course as well as the time of the year most convenient for him to have this work.

Tentative outlines for three courses are herewith submitted. It is expected that the registration fee will be \$10.00.

THE DAILY PRESS

WOMAN'S AUXILIARY OF OUEENS COUNTY

The New York *Times* of March 22 contains the following news item regarding the Woman's Auxiliary of Queens County,—the first to be formed in New York State:

"The Women's Auxiliary of the Medical Society of Queens County, the first organization of its kind in New York State, was formed yesterday at the organization meeting at the Medical Society of Queens County Building, 112-25 Queens Boulevard, Forest Hills. Following addresses and the signing of the charter by 100 wives of members of the society, Mrs. Claire T. Bearnstein was elected president.

"The meeting was called to order by the temporary chairman, Mrs. Ruth Mencken, wife of Dr. Harry Mencken, president of the society. Mrs. William M. Stone was temporary secretary.

Doctors' wives are looked upon as leaders in the community, in welfare groups and in mothers' clubs,' said Mrs. N. Roy Van Ness, past president of the New Jersey State Auxiliary and the Essex County (N. J.) Auxiliary, emphasizing that social functions must not be the most im-

portant activity of the auxiliary. 'You can act as a liaison between organized medicine, as represented by the county medical society, and the public and can take an active part in stimulating health projects.'

"Dr. Mencken said an anxiliary was capable of filling the breach between the doctors and the public in advocating health measures which the ductors, because of their positions, could not propose. He also traced the history of the auxiliaries of the medical society until a national organization was formed and said there were sixty county medical societies in New York State.

"The following were elected officers of the

auxiliary :

"Mrs. Bearnstein, president; Mrs. Ruth A. Mencken, first vice president; Mrs. Lillian Victor, second vice president; Mrs. Katherine Lavelle, third vice president; Mrs. Constance McManus, fourth vice president; Mrs. Katherine M. Stone, recording secretary; Mrs. Gertrude Lipton, corresponding secretary; Mrs. Margaret Rnbbins, treasurer.

HEALTH AND THE DEPRESSION

The New York *Times* of April 11 discusses health and the depression in the following editorial:

"Health conditions for last February in New York State were substantially the same as a year ago, and February, 1932, had the best showing on record for that Winter month. The death rate for infants under 1 last February was a trifle higher than in the corresponding month a year ago, but it was better than in any preceding February. This is one more bit of evidence that more than three years of business depression have

not taken heavy toll of the health of the community. The third full year of depression, 1932, was the best health year we have had. The current year is apparently going to be as good.

"It is often said in apology for grandiose antidemocratic experiments in government and sociology involving misery and cruelty for countless millions that we must think of the benefits which will accrue to their future generations. This country, in the heart of an economic blizzard, is seeing to it that future generations shall not suffer. Our school and health statistics attest it."

DISEASE GERMS AS BULLETS

The New York Sun of February 20 comments on an article on "Induced Epidemics in Warfare" which appeared in the Medical Journal and Record of February 15, 1933. People are frequently aroused by reports of the discharge of disease germs upon a city or army. The Sun allays these fears in the following editorial:

"Discussing the practicability of intentional communication of infectious diseases, the Medical Journal and Record says there is no doubt that it was attempted centuries ago for criminal

purposes. According to this authority the first authentic record of its proposal for use in war is attributed to an English officer who, in the 1700s, suggested the spreading of smallpox among the Indians of Nova Scotia by means of blankets infected by victims of the disease. Technically, the Journal and Record holds that the introduction of disease in enemy forces which, it says, is 'regarded nowaddys as a certitude by the German the Italian and the Russian governments' sents a number of difficulties:

The Sun comments on the very great difficulties of keeping bacteria and viruses alive until they could reach their victims, and closes the editorial with the following comment, encouraging and reassuring:

"The conclusion reached by the Journal and Record is that 'we may well believe as Nicolle

stated in his recent work "On the Genesis, Course and Extinction of Infectious Disease" that "whatever the genius, whatever the wickedness of man, problems of this nature are fraught with such enormous difficulties that wickedness, aye, and genius are bound to be foiled." It is a conclusion the civilian population will be glad to share."

WORLD CONTROL OF NARCOTICS

The New York *Herald Tribune* of April 13 has the following editorial on the international control of narcotics:

"The narcotics-limitation convention, which was signed at Geneva by the representatives of twenty-eight governments on July 13, 1931, narrowly missed going by default today. A year and a half was allowed in which to secure the ratifications of four drug-manufacturing and twentyone other states. A few weeks ago the United States was the only drug-manufacturing state that had accepted the treaty, and it was indorsed by no more than fourteen others. It then began to look suspiciously as though the European manufacturing countries which fought the convention so bitterly in 1931, because it threatened to impose an effective check on a lucrative illicit traffic, had determined to kill it by the simple negative device of letting the time limit on ratification expire. It will, therefore, be a source of sincere satisfaction to the medical fraternity, the police and welfare workers of every kind in every civilized country to understand that twenty-six ratifications had reached the League secretariat on Monday and that the convention is therefore automatically binding today upon all its signatories.

"The system of control which the American delegate, Mr. John K. Caldwell, and his colleagues had these twenty-eight nations adopt in 1931 is unique in the annals of international relations because it endows a League of Nations committee with a degree of sovereignty over the domestic industry and commerce of the signatories which has never before been surrendered to the

League or any similar organ. Each nation submits to the League an annual advance statement of the narcotic drugs required for legitimate medical and scientific purposes, together with an account of reserve stocks, of orders placed for supplies and of orders received by its manufacturers. The totals must, of course, tally, and all permits are then issued by the central control committee. To this committee and to the other parties to the covenant the signatory governments are then responsible for and in a position to check any leakage of manufactured drugs into the channels of the illicit traffic.

"The final ratification of this unusual agreement is a great triumph for a cause that has always had much more powerful and highly organized opposition than support. Addicts, peddlers, smugglers, manufacturers and their governments have always conspired with great success to surround the devastating 'dope' trade with inviolable secrecy. The struggle against it, conducted largely by limited professional groups, therefore enjoyed no great publicity until the League furnished a stage two years ago on which the devices by which the European governments hoped to shield their manufacturers from effective control were exposed to the world and made duly That the signatures disgraceful by publicity. then secured have now been ratified in good faith without further pressure is satisfactory evidence that the airing which the narcotic problem received in 1931 aroused a new sense of governmental responsibility throughout Europe for the most nefarious of all traffics and that the end of that traffic is at last in sight."

INDIVIDUAL TASTES

Every doctor understands the necessity of catering to the individual tastes and preferences of his patients, and will agree with the opinion

I know of a farm by the side of the road
Where the robins are singing their songs
And the musical frogs
Hidden deep in the bogs
Are chorusing night and day long.
And there, if I tire of the tumult of town,
Whose turmoil seems never to cease,
I know I can find
A serene peace of mind
And the perfect contentment of peace.

which James J. Montague expresses in the following verses from the New York Herald Tribune of April seventh.

I know of a number of places like this—Green hills, or wild mountain retreats Or forest-hid nooks,
Filled with music of brooks,
And remote from the echoing streets.
In fact, there is many and many a spot
Where I might, if I liked, settle down
And renew my lost youth,
But, to tell the plain truth,
I would much rather dwell here in town.

BOOK REVIEWS

DIAGNOSIS AND TREATMENT OF DISEASES OF THE THYROID GLAND. By GEORGE CRILE, M.D. and Associates. Octavo of 508 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$6.50.

A remarkable, comprehensive symposium concerning the most interesting and fascinating subject of medicine, surgery and their allied specialties. Dr. George Crile writes 14 of the 39 chapters. The remaining 25 chapters are ably handled by an array of authoritative and special talent.

Thyroidectomy is advised for hyperthyroidism during the course of—1. Active Pulmonary Tuberculosis. 2. Diabetes Mellitus. 3. Syphilis. 4. Pregnancy, regardless of its stage. 5. Arthritis, especially of the spine and shoulders. Separate chapters on these complicating diseases impart valuable information.

Essential hypertension and rheumatic carditis may mimic hyperthyroidism. The reader is warned against

advising thyroidectomy in these cases.

A chapter by Dr. Crile on the adrenal factor advises a two stage denervation as a preventive against a residual or recurrent hyperthyroidism. He reports 24 such operative cases with apparent cure. Note that in a more recent paper, Dr. Crile has added a third indication and reports 21 additional adrenal denervation cases of severe primary hyperthyroidism too sick for thyroidectomy. A more detailed description of the adrenal denervation operation would probably have enhanced an already valuable book.

Medical and x-ray therapy of hyperthyroidism are impartially presented. There are 22,441 operative cases listed. For the last 5,000, a mortality rate of 0.84 per cent is reported. With such a remarkable record, Dr. Crile justifiably claims for operation the only safe and rapid cure for hyperthyroidism.

This indispensable volume is a culmination of unselfish endeavor in a crowning achievement of Medicine and Surgery, through a long list of historic names from Theodor Kocher to George Crile.

HARRY FELDMAN.

LABORATORY SERVICE AND THE GENERAL PRACTITIONER. By Arnold Renshaw, M.D. 12mo of 267 pages. New York and London, Oxford University Press, 1932. Cloth, \$2.50. (Oxford Medical Publications.)

The title of this book, Laboratory Service and the General Practitioner, summarizes briefly the purpose of this valuable text. The reader is impressed with the effort which the author makes to guide the practitioner in seeking the assistance which he can obtain from the laboratory. The important available laboratory methods are briefly and explicitly described with examples in normal findings appended to each test. In order to aid the physician in avoiding unnecessary tests, the author includes an appendix in which are listed the more useful laboratory examination which should be made in cases coming or believed to come, under the condition mcntioned, the latter being placed in alphabetical arrangement: Thus, under C, one finds "coma" with the following suggestion. Urine—for sugar and acetone, blood urea estimation, blood film for malaria if associated with pyrexia. About 250 conditions are thus listed, each with suggestions of the laboratory tests to be employed.

In reading through text books on this subject, one is impressed with the growing needs for the clinical pathologist who functions as the link between the clinician and the laboratory, a link which is too often missing.

SILIK H. POLAYES.

MANUAL OF EMBRYOLOGY. By J. ERNEST FRAZER, F.R.C.S., Eng. Octavo of 486 pages, illustrated. Baltimore, Williams & Wilkins Company, (William Wood & Company), 1932. Cloth, \$8.00.

The plan of this interesting book differs from that of previous texts on this subject in that the now rather universal plan of teaching anatomy by the regional method is followed, with the result that embryology, histology, and gross anatomy may be considered simultaneously. The subject has been divided into two parts, part one being devoted to early and general development dealing with the formation of the embryo as a whole and in itself forms a text of general embryology. Part the deals more specifically with the development of organs and regions and can be used as a reference section by the physician who is especially interested in one definite region, in this way enabling him to round out his knowledge of his specialty without wading through a mass of information regarding other structures whose only relationship is that of chronological sequence. The book is well illustrated by diagrams and drawings, many of which are original. The printing is up to the standard set by the publishers.

Injuries of the Eye. By Harry Vanderbilt Würde-mann, M.D. Second Edition. Octavo of 900 pages, illustrated. St. Louis, Mo., The C. V. Mosby Com-pany, 1932. Cloth, \$13.50.

Relatively well-known facts set down from an unusual

viewpoint, may be as valuable as new facts.

When we buy a new book nevertheless, we subconsciously at least want it to contain information not found in books already in our possession. Besides this, we feel a particular interest in a book well illustrated and well printed.

We can say that this second edition of Würdemann's work abounds in these three features. There is a pleasant blending of new and worthwhile old material with a wealth of satisfactory illustrations which appeal. The diction is pleasing, and the presentation of the material is logical and clearly set forth. We can have the greatest confidence in a writer of such broad technical experience, such great ingenuity, and of such versatility in literary and artistic expression.

Reference to his chapters on operative injuries, artificial cyes, injuries to the visual nervous system, he departs somewhat from the traditional in his remarks on phynology and anatomy and injuries of the lacrimal apparatus will be found to contain not only new material and material not found in other works, but will provide a very interesting viewpoint of pictures met with in daily practice. In Part III Dr. Würdemann has collected a great mass of data on forensic medicine which is not available in other works on the eye. There are sections on the physician in court, malpractice, a digest of workmen's compensation laws of the world, and a great variety of other topics which are of the greatest interest and value to the ophthalmologist. All this material is authentic and as up-to-date as is possible with the everchanging material of this type.

The illustrations are clear and demonstrate very well the points which the author wishes to make clear. All in all this book is a real addition to the library of every ophthalmologist, plastic surgeon and industrial surgeon. It should be on the shelves of every hospital for reference not only by the surgical staff but by the executive staff of the institution.

JOHN N. EVANS.

DISEASES OF THE SPINAL CORD. By WILLIAMS B. CAB-WALADER, M.D. Octavo of 204 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1932. Cloth, \$5.00.

In this book we have a timely addition to the growing literature on spinal cord disease.

The first two chapters are devoted to the neuron theory and an anatomical review of the content of the spinal cord including pathways and circulatory supply.

The third to fifth chapters are utilized in describing the elicitation of neurological signs and their significance; similarly with symptoms. In describing symptomatology and physical signs, there is correlation with the previous anatomical description, to indicate how a determination of the level of a spinal cord tesion is arrived at.

In the remaining ten chapters, specific diseases are discussed. Each disease is treated systematically with reference to ctiology, pathology, symptoms, progress and treatment. Particularly good is the discussion of compression myelitis.

The book is liberal in its illustrations. There is an extensive hibliography. It is well suited to the needs of the general physician.

STANLEY S. LAMM.

EXCITABILITY—A Cardiac Study, By W. BURRIDGE, D.M., M.A. Octavo of 208 pages. New York and London, Oxford University Press, 1932. Cloth. (Oxford Medical Publications.)

This volume consists primarily of the elaboration of a new theory of the processes involved in excitability and contraction based on cerlain experiments performed on perfused hearts. The theory is also later applied to all fundamental physiological processes. The views are so nuch at variance with the accepted principles of physiology that they cannot be accepted without a great deal of independent corroboration.

J. H. Crawford.

AN INTRODUCTION TO ANALYTICAL PSYCHOTHERAPY. By T. A. Ross, M.D. Octavo of 203 pages. New York, Longmans, Green & Company, 1932. Cloth, \$350.

This book is precisely what its title implies, an introduction to analytical psychotherapy. The author has had a rich experience in treating neurotic patients. He has familiarized himself with all recognized forms of psychotherapy, and apparently is learning towards the Freudian doctrines. In fact, he has acquired considerable knowledge in Freudian principles, but consciously seems to rehel against accepting them completely. Nevertheless, the books serves as an illuminating exposition of psychoanalysis. He discusses at length such topics as the unconscious, transference, dreams, sex problems, symptom formation and technic.

This book is highly recommended as it briefly and lucidly presents the analytic approach in the management of the neurotic patients.

INVING J. SANDS.

ERDMANN'S CLINICS. Excerpts Selected from the Clinics of John F. Erdmann. By John F. Erdmann, M.D. Octavo of 315 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$4.50.

The Saunders Company has just issued a most interesting volume based on the Clinics of Dr. John F. Erdmann of New York. The material in this compilation is based on the forty years experience of Dr. Erdmann in his work, both private and public, in New York Gity. Part of it is didactic and given in lecture form in a most illuminating way, covering not only the surgical aspects of the lesions, but the gross and microscopical description of the same. Another part is composed of descriptive remarks made at the time of operation which also adds much to the value of the work. The whole work covers

the Sirgery of the Abdomen and Pelvis, both male and female, to which is added Breast Surgery and short chaplers on Hemorrhoids, Ilernia, etc. The work as stated is the expression of Dr. Erdmann in relation to his own experience and where he may differ with othere as to technique and choice of methods he gives reasons to justify his position. The book is deserving of careful s'udy and is arranged so that subject matter is classified, and reading may be done at odd times without losing the continuity of thought.

Eugene W. Skelton.

CLINICAL GYNECOLOGY. By C. JEFF MILLER, M.D. Octavo of 560 pages, illustrated. St. Louis, Mo., The C. V. Mosby Company, 1932. Cloth, \$10.00.

The author has designed this book to serve as a companion volume to his "An Introduction to Gynccology," and it is intended for the student who is just beginning his study of gynccologic therapy. The discussion of pathology, symptomatology and diagnosis is purposely avoided.

The book is divided into three parls,—Part I deals with gynecologic diseases and their treatment. Part II considers therapeutic measures in gynecology, and Part III is devoted to operative gynecology. The text is accompanied with many excellent illustrations.

While this excellent text book is primarily intended for students, those of more mature years will find much of great value, both in the clear and concise suggestions so to therapeutic measures, and in the discussion of various gynecologic operations.

W. S. SMITH.

THE EARLY DIAGNOSIS OF THE ACUTE ABDOMEN. By ZACHARY COPE, M.D. Sixth Edition. Octavo of 248 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$3.25. (Oxford Medical Publications.)

This little book of two hundred and forty odd pages has reached its sixth edition in ten years; really nine editions because there has been a second impression of three editions. It is therefore provably a useful book. Though a considerable number of minor alterations have been made in this edition the scope of the book has not in any way been extended.

The book deals solely with the early diagnosis of the acute abdomen. It is a book for the general practitioner as well as the young surgeon.

The author has had a very extended experience in acute abdominal surgery and has been particularly fortunate in seeing a sufficient number of such cases in the early stages.

The book is clearly and pleasingly written, and if it is read by the general practitioner with understanding, serves an extremely useful purpose. It is well indexed so that its contents are readily accessible.

RUSSELL S. FOWLER.

Anatomy of the Brain and Spinal Cord. By William W. Looney, M.D. Second Edition. Octavo of 370 pages, illustrated. Philadelphia, F. A. Davis Company, 1932. Cloth, \$4.50.

In writing this book, the author has had in mind several important points and has succeeded in fulfilling the requirements. The book is intended to be a text for first year medical students. The author believes that as such, it should be simple in its description and arrangement of material but at the same time it should cover the subject. Throughout the text he has carried in mind the importance of arousing and maintaining the interest of his students. In this second edition many sections have been entirely rewritten and errors climinated. We believe that this type of textbook is to be desired.

O. C. PERKINS.

OUR NEIGHBORS

STATE HEALTH DEPARTMENT OF TENNESSEE

The February issue of the Journal of the Tennessee State Medical Association prints a bill proposed by the Association for reorganizing the State Department of Health. It provides for a council of seven members, six to be physicians nominated by the State Medical Association and one dentist nominated by the State Dental Association.

The Council shall elect a Commissioner of Health. It shall also formulate the policies of the Department by which is probably meant

the enactment of a sanitary code.

Commenting editorially on the proposed bill

the Journal says:

"This bill will be introduced when the Legislature reassembles. In the meantime local medical societies should explain this bill to their representatives in the House and Senate and secure their support of it. This should be done now.

"The following are a few of the reasons why this bill should become a law: First, the Commissioner of Public Health under existing statutes has more power than should be vested in one man. His powers are almost limitless in so far as health policies and health regulations are concerned. For this reason there should be a Board of Directors whose duty it is to make the regulations and formulate the policies to be followed by the various executives of the department.

"It is not the purpose of the medical profession in sponsoring this bill to destroy the health department or its effectiveness. It is rather our desire to see that sound policies are formulated and followed. It is believed that economies can be affected and the usefulness of the department increased at the same time.

"Sound policies of administration will remove the causes for the growing conflict between the practitioners of medicine and the public health agencies. This is a vital consideration. The practitioners of medicine who take care of sick people, who make the first contact with contagious diseases of all sorts, are the most vital public health agencies in the state. To destroy their interest in public health by following unsound and unnecessary public health policies financed by large appropriations have a disasterous effect. It has the effect of destroying the greatest public health agency we have, and of bringing about the necessity for still larger appropriations for public health departments and the creation of more bureaus. By such steps the medical profession and the public become engulfed in bureaucracy.

"Every one recognizes the need for a public health department clothed with the authority to exercise those powers which only an executive of the State can exercise. These powers should be preserved and vested in a board who will exercise them judiciously, in the interest of public health, in the interest of economy, and in the interest of preserving the institutions and principles of government which makes ours a free country.

"We must arrest our march toward bureau-

cracy or our freedom is gone."

MEDICAL LEGISLATION IN SOUTH CAROLINA

The February issue of the Journal of the South Carolina Medical Association contains the following editorial on the legislative needs of South Carolina:

"The so-called economy legislature is now in session. At the present moment the chief concern of the medical profession in South Carolina is the attitude of this body towards our educational institutions, notably the Medical College. As the appropriation now stands the Medical College will suffer tremendously in the event that this appropriation cannot in some way be increased. We wish to emphasize the necessity for every doctor in South Carolina taking up the matter personally with his delegation and explaining the whole situation with reference to the demands of medical education for the highest type of teachers. Our

State Medical School is probably run more economically now than any other Class A medical college in the United States. More than half of the doctors in this State received their training there, and doctors are decreasing in this State in numbers every year. We have now a lower ratio of doctors per population than any other State in the Union. It is readily seen that a good medical school maintained at a high level is one of the most important considerations before us at the present time.

"The legislative program for health activities very likely can stand some modification in certain phases of its work without serious consequences. It cannot be denied that the Legislature in general has done a great deal for the health of the

MANGANESE

PHOSPHORUS

An Aid In Fighting Chronic Sepsis

Chronic cholecystitis, chronic prostatitis, chronic colitis are but a few of the rather common conditions which give rise to a state of chronic sepsis.

Fellows' Syrup has proved to be of decided value in aiding the fight against the constant septic factors. Its ingredients: Manganese and Iron regenerate the impoverished blood stream; Calcium re-excites the dormant defensive mechanisms; Sodium, Potassium and Phosphorus overcome the troublesome psychoasthenic elements; Strychnine is of value as a stimulant to the respiratory asthenia; and Quinine is a distinct metabolic stimulant.

Fellows' Syrup in these conditions supplies the required mineral elements. The dose suggested is one teaspoonful in half a glass of water four times daily.

(Continued from page 616-adv. xii)

"There are more than 1,500 licensed physicians in active practice in this state today. Each physician spent approximately \$10,000 on his education and gave up approximately seven years to preparation and study. We have, therefore, an investment of some fifteen million dollars in medical education in the state. We have, in addition, an investment of more than 10,000 years of scientific study behind the medical profession.

"This colossal investment in time and money, built up for the protection of our citizens, is the result of more than sixty years experience under our medical practice act. We can not believe that the legislature of West Virginia will ignore such an investment. Certainly it is not consistent with sound judgment to say that one group (the medical profession) must spend years of study before being allowed to treat the sick, and that another group (the Christian Scientists) can go ahead without any preparation whatever."

BASIC SCIENCE LAW IN COLORADO

The March issue of Colorado Medicine contains six pages on the subject of a Basic Science Law, such as was adopted in Wisconsin eight years ago, and since that time in Connecticut, Minnesota, Nebraska, Washington, Arkansas and the District of Columbia. The proposed law for Colorado fills two and a half pages of the Journal, and would require examinations in anatomy, physiology, pathology, chemistry, and bacteriology.

Commenting on the law the Journal says:

"An important feature of this measure is that the projudices of drugless healers against examination by medical boards are entirely climinated. Likewise the distrust of medical practitioners in the ability of drugless healers to conduct adequate examinations in the fundamental sciences is avoided. This is accomplished through provision that the Board of Examiners in the Basic Sciences shall be made up of educators, shall have on its membership no person engaged in the practice of any branch of the healing art, and no more than one member out of the five who is an advocate of any one school of thought in healing.

"The Basic Science Law ignores differences in preprofessional education by allowing high school

graduates to be examined.

"Persons who pass the examination held by the Basic Science Board are given certificates to that effect. Such certificates do not entitle them to practice, but merely authorize their admittance, on compliance with other necessary requirements, to examination by whatever one of the several professional examining boards each applicant may (Continued on page 620-adv. xvi)

NEW TREATMENT FOR STRYCHNINE POISONING

In three years, 1926-1928 inclusive, there occurred more than three deaths a week from strychnine poisoning in the death registration area of the United States. The commonest cause of death from strychnine poisoning is a drug-store commodity, the chocolate-coated or sugar-coated laxative or tonic pill or tablet, stored carelessly in the house within the reach of children.

Observations and experiments conducted by Drs. G. F. Kempf and L. G. Zerfas, members of the Lilly Research Staff, and Dr. J. T. C. McCallum, a former member of the Lilly Research Staff, warrant the conclusion that Sodium Amytal, Lilly, is an effective antidote against strychnine poisoning. The physicians found that Sodium Amytal, Lilly, could be given in large doses without bad effect. It stopped the convulsions promptly, put the patient to sleep without interfering with his breathing. For use as an antidote where prompt effect is highly desirable, Sodium Amytal, Lilly, should be given intravenously. Its effectiveness by mouth, however, has already been demonstrated.—Adv.

VICHY CELESTINES

The Medical Profession will be interested to know that the Vichy Com-

pany of Paris has given special consideration to the needs of the individual physician, wherever located, in obtaining supplies of Vichy water for himself and his patients.

In order to facilitate the distribution in this country, the American Agency of French Vichy, Inc., 503 Fifth Avenue, New York, has been appointed Sole Agents for the United States.

The Vichy Company of Paris has expended large sums on improvements recently completed, at the bottling establishment at Vichy, whence the famed natural mineral water from Celestins Spring and also from the Grande-Grille and Hospital Springs is shipped to all parts of the globe.

Many American doctors have visited Vichy in France and have been impressed by the fact that patients, while taking the cure at the baths and the springs, can while away the time enjoyably at golf, tennis and other sports and enjoy the unexcelled attractions of the Casino and the beautiful Opera House.—Adv.

MÜNCHENER MEDIZINISCHE WOCHENSCHRIFT

Dr. Kurt Ochsenius

"Zur Behandlung der Broncho-pneumonias in Early Childhood"

The author states at the beginning of his article that the treatment of gastro-intestinal catarrh of infants has advanced considerably during the last years and that Cholera infantum, previously so much feared, can be successfully treated, even during the summer season. The next problem in pedi-

atrics the author sees is the successful treatment of broncho-pneumonia is early childhood which is still said to show a mortality as high as 80 per cent.

Next to proper prophylaxis the author recommends a continuous change of position of the infant, and the application of hot kataplasms which will retain the heat for hours, and also preparations of quinine. This treatment was successfully applied in 50 cases and the author therefore believes Antiphlogistine to be the ideal method of applying continuous moist heat.—Adv.

GOLF, AND INFANT FEEDING

It is possible to play over the entire course with a single club and bring in a fair score. But playing with only one club is a handicap. The best scores are made when the player carefully studies each shot, determining in advance how he is going to make it, then selects from his bag the particular club best adapted to execute that shot.

For many years, Mead Johnson & Company have offered "matched clubs," so to speak, best adapted to meet the individual requirements of the individual baby.

We believe this a more intelligent and helpful service than to attempt to make one "baby food" to which the baby must be adapted.—Adv.

MEDICAL SERVICE FOR THE NATION By EDWARD H CARY, MD, DALLAS, TEXAS

An address by the I resident of the American Melical Association deliverel at the Annual Meeting of the Medical Society of the State of New York after the Annual Ranquet on the exenung of April 4, 1933 in the Hotel Wallorf Astoria New York City

FOUR hundred years before Christ, the medical profession was given a law by Hippocrates Although twenty-four centuries have elapsed, this law contains for its all the essential elements to guide and hold us. It is the rich earth from whence the Tree of our Order has sprung

It is too, the background of medical tradition worth treasuring. In our history we have not departed appreciably from the tenets of this law, and they have survived because Hippocrates was able to sum up the fauidimental principles which should govern those whose profession is medicine.

In the last paragraph of the Law wherein he stated, "Those things which are sacred are to be imparted only to sacred persons, and it is not lawful to impart them to the profane until they have been initiated into the mysteries of the secence," he established a principle which has been followed faithfully. Inventions have been given by the discoverers to followers of the healing art, just as all scientific knowledge has been revealed. The improved technique of medicine has become the property of all who cultivate the art and science of medicine.

It is an interesting circumstance that of all the associations of men who for centuries have bound themselves together for a common purpose the profession of medicine is the only one which has grown stronger and more digmfied through the years

It has survived as an entity because of the bisically sound policy of the distribution of knowledge, imparted by its members each to the other for the purpose of serving the human race

Medicine readily becomes an instrument of the brotherhood of men who are engaged in properly interpreting Nature's secrets

Medicine, both a science and an art is gloriously stimulating for it lays bare the gamut of human emotions

The science of medicine bridges human eccen tricities and all ethnological circumstances

Disease affects individuals differently depending upon the immunity acquired. Cellular reac-

tions in human beings, when observed and recorded, represent widespread experiences

The true scientist develops a extrain quality of nind, for while deling and searching for genis of truth, his mind becomes attitued to Jeliovah's purposes. The patient worker builds a pathway with fact after fact honorably placed for the pageant of excilization to mount upward and onward. Sometimes the builder is not well known and remains unsuing regardless of nationality. His own reward is a glimpse of God expressed in the infinitely small or maybe, in the infinitely great

Conjecture as you may, we believe that this is a real reward for men who toil in every Nation of our far flung Universe, for they are interpreting facts, and constructing the Roadway of

Medicine has liad its allies both in the men who developed the basic sciences and those who rightly interpreted them. Open minds, with ready wit, and a capacity to inform the world through literature as did Voltaire, Franklin, and others, quickened the acceptation of scientific truths as they were developed.

The science of medicine, as we know, gained its greatest impetus with the discoveries which rapidly followed the work of Pasteur, who revealed the heretofore invisible but important factors of life to an astonished world. From that time on, the etiology of disease could be proven experimentally, and as one discovery after another of the causes of recognizable diseases became known medicine lost much of its superstition and developed true scientific merit.

The thirst for knowledge became the ruling factor in medical education and this incentive is the binding force which underlies the progress of the medical profession

The law of Hippocrates has been a determining factor in holding men to ethical standards for it expresses particularly the nobility of the art and emphasizes the necessity to word ignoble practices

The Father of Medicine has made it possible

for us to adjust the practices of tomorrow by using the yardstick of his tenets to measure the conditions of the modern world.

Suppose we turn our attention to the influence of modern conditions upon material and ethical problems in medicine as we find them today. We cannot ignore the higher cost in time and money necessary to create competent physicians. The modern medical man is confronted with an evergrowing science which often develops more rapidly than he can encompass the art of medicine as expressed in its practice.

Today we face an ever-increasing army of modernly educated physicians most of them seeking to discover through research in laboratories and thinics, the cause of disease. This vast army is ready to apply acquired knowledge to prevent the recurrence of diseases which engage their time and bring them a livelihood. We recognize already a lessening demand for the men of our profession. Preventive medicine has eliminated many diseases which once occupied the profession's attention. Sanitary laws and immunization, the result of professional knowledge and agitation, are rapidly making life safer in all localities; a contribution so great that the people now think of the state instead of the medical background.

It would be inconceivable for the medical profession to fulfill its high task in the service of humanity if it were not working as an organization, having fixed principles to guide it. The people should know this and if they were properly advised, they would sustain any effort on the part of medical men to build a strong responsible association for it conserves the health of the people.

Nothing should be permitted to destroy harmony of action within the profession. The well-being of humanity is intimately associated with the high ethical concept adopted and preserved by the medical profession to sustain its own nobility and its interest in the people's welfare.

Eliminate the application of accurate medical knowledge through ill-considered economic practices to the point of conceivable diminishing monetary returns, and the progress of medicine will in a large measure become an abstract science; of value as an intellectual pursuit but deprived of an important human incentive which has so definitely made the application of the science and art of medicine serviceable to humanity.

Today society is so complicated that if medical knowledge lagged or ceased to progress, it is conceivable that society as we know it, would wane and the human race be left to struggle with the recurring pestilences of the past. Education, the great motif, underlying medical organization furnishes the cementing force which unites men to a common purpose.

In 1902, the American Medical Association was organized as a modern expression of the sentiment which has held medical men together

as a body throughout the ages. Medical men believe in the elevating quality innately existing within the profession. Seemingly it is true that the educated physician in any age has been a superior man; though exact scientific knowledge may have been lacking there was something enobling in the study and traditions of medicine, which caused men to catch a real vision of life's values.

There was simple living and high thinking. There has been orderly evolution however, in the construction of the Roadway of Scientific fact.

An organization such as the American Medical Association, must necessarily have a code of ethics, and although our code is the outgrowth of tradition, it is a modern expression of our desire to relate our interest to the people, and serve them in a uniform manner. It does not abridge the rights of any man and as a living manifestation of ethical restraint, it can be viewed triumphantly for the golden thread of moral and spiritual values can be traced through all medical history.

Conservatism is a normal view of the average practitioner. Any change in method of practice is resisted until it becomes clearly apparent to the majority in a locality that change is necessary. Social trends may be recognized and yet the medical man will be slow to adopt new methods. Such conservatism is normal and in the broadest sense, is probably for the good of society.

If it be true that society is best served by a great profession not easily swerved from its ideals and mode, then society should be willing to have any proffered plan to revise medical practice thoroughly discussed and made genuinely sound before a radical change is adopted. The time necessary for a solution should be conceded by society.

Organized medicine believes that it has several definite functions: first, and most important, to perform the practice of medicine, and when this is said, we mean actual contact with individuals who are sick.

Influenced by economic urge, any mechanism which tends to destroy the intimate relationship between the doctor and patient, will find its reflex in disturbed professional service, destructive to human satisfaction.

We believe that as an organization, it is the duty of the American Medical Association to protect *individualism* in the practice of medicine, and it is wholly logical for us to resist socialization of medicine from any source.

We readily perceive however, that there are superficially informed persons, who would have medical men less individualistic. They would place him in groups under a leadership which would tend to destroy his right of self-determination in the practice of medicine. We believe such a condition would lessen his initiative and develop a tendency to mechanize medi-

cine. If so, the contact of patient and doctor would become less intimate and the true story which every patient wants to tell, would remain in many instances, unrevealed.

We agree with Dean Schwitalla that no one should stimulate a movement toward coercing medicine through social stress as an economic need. It is fallacious to believe that an organized group is immediately endowed with extraordinary capacity. It depends after all upon the members comprising the group aud the amount of individual attention given to the patient by the individual doctor, who should be deeply and personally interested. This function can be performed in or out of a group. While medicine has to adapt itself to human needs, we must not lose sight of the first law of nature which is self-preservation.

Because doctors have felt that healing the sick is a sacred trust; because the very nature of their work requires that they put their time, their strength, their skill and their very life, at the call of humanity, they cannot view with comfort the prospect of radical change in their present plan of practice. No one knows better than the doctor the need for an intimate understanding of the patient's background. To obtain this information the physician must often become the possession of the sick individual. The medical profession cannot be Fordized until human beings become robots.

We believe that it is the function of organized medicine to promote preventive medicine and public health work; primarily this means the education of the public.

Though statements to the contrary have been made, there has been an abundance of medical leadership, deeply interested in magnifying public health measures. Through the units of our organization, and through our state medical associations, all of the information believed to be acceptable to the public, is being constantly and systematically given to the people through professionally supported public health agencies and by doctors who make popular health talks, radio talks and through thousands of articles given to the press. All of this is in the interest of public health in an effort to prevent disease.

The American Medical Association early in its career had among its members, a few medical statesmen who planned wisely for us. Those of you who are familiar with the work of our Councils and Bureaus, not only in education, but in pharmacy and cliemistry and many kindred departments, recognize the far-reaching influence these councils have had in the protection of the people through high standards in medical education, pure food and drug laws, and the standardization of pharmaceutic preparations.

Through the work of our council and committee, the manufacturers of food products have

found it wise to revamp their advertising. Spurious claims in many instances have been eliminated. Over seven hundred products have been submitted to our Committee on Foods. When this Committee sanctions a statement or revision, the manufacturer is permitted to advertise the approval of the American Medical Association.

Certainly this supervision is stimulating the purveyors of food products to a higher conception of their responsibility to the people, who are themselves, looking for the American Medical Association stamp of approval in featured advertisements of packaged products.

We believe that this method of ours based upon scientific investigation, followed by approved publicity, is far more effective than a statuatory enactment enforced through process of law. This is but one of the many active programs for the promotion of public health education.

Pseudo-scientific claims paraded as cures for some of the most serious diseases which affect humanity are not so boldly exaggerated today as formerly. A well recognized human trait is optimism and there are few persons suffering with a chronically fatal malady who will not believe the most improbable promise of cure.

To combat the vultures who are perfectly willing to prey upon humanity, it has required more courage and money than the average doctor or small medical society could afford. The American Medical Association has assumed this task and Medical Association has assumed this task and medical is knowledge, its accumulated monetary surplus, and its determination, to save human beings from such exploitation. Of the numerous suits for libel tried at a cost of thousands of dollars to the Association, not a single case has been lost.

Such protection for the profession and the public is invaluable!

Boldly pursuing this policy, we make it possible for the secular press to condemn evil practices.

Another function of organized medicine is to foster research and through new discoveries, increase our knowledge. Research has been definitely encouraged. We provide money for grants which some three hundred workers are now using. To further this phase of endeavor, our organization is well supplied with journals of the first rank.

Our own American Medical Journal, the greatest of all journals, like a planet has its satellites in Special Journals to stimulate interest in specific subjects. State Journals greatly reenforce the work and aid in the distribution of knowledge.

In conjunction therewith, the *Index Medicus* published quarterly at a considerable cost to our organization, offers an available and accurate index to the literature of the world, and its use conserves both time and money for the man who seeks information.

It is needless to refer to what has been accomplished by the standardization of our medical schools. Unqestionably there has been a vast improvement in the quality and educational equipment of the doctor of medicine, and correspondingly, we have raised the social standing of the physician.

In magnifying the advantages of the practice of medicine, we have attracted a far greater number of the highest type of young people than can be assimilated at this time. This era which brought much in educational accomplishment has evolved material changes in economic values both in urban and rural sections creating a mutual problem for the physician and the people.

The number of medical graduates plus those who come from abroad, exceeds the mortality of our profession in numbers sufficiently large to alarm the practitioner as to the proportionate dis-

tribution of doctors.

We recognize the curtailment in population, due probably to artificial barriers interposed both in home life and restricted immigration laws. This economic problem would seem to be of equal gravity to the Medical Body, and to the Public.

Any retardation in distribution of proper medical service in communities is not necessarily the fault of the Medical Profession, but is a characteristic social phenomenon which has always

existed.

Adjustments are more necessary now however than heretofore; the instances of diseases so prevalent a few years ago have decreased—some of them have been entirely eliminated. The public has been educated to the value of the applied sciences. Medical practitioners find their clientele frequently looking to the public health authorities for preventive measures and services which the practitioner should perform. It has been said that this is the result of a lack of interest on the part of members of the profession.

The Commissioner of Public Health in Detroit is intelligently using the medical profession and has awakened an interest among the doctors in the prevention of disease which has been of decided advantage to the citizens of Detroit as well as to the physicians. He has made of each doctor's office a community health center. Public health officials everywhere should likewise cooperate with the leaders of the medical profession

in the various localities.

Not only forty per cent but eighty or ninety per cent of the children in a community should be immunized. This can never be done by the Public Health authorities without great detriment to the medical profession unless the two forces cooperate.

It is generally recognized that good health is one of the important necessities of life. With physical vigor, a people may be happy and through contentment one might visualize prosperity. Rependency and unemployment often

follow in the wake of sickness. Since health in a measure can be purchased, we must realize that a country which habitually attempts to regulate its industries, and has developed universal education at the expense of the people, is liable to make an effort to conserve and improve their health, through similar regulatory measures.

It remains to be seen whether the medical profession will provide the leadership to guide and

direct this social trend.

The economic situation at this time has stimulated a widespread interest in evolving a plan to meet the present condition. Though it is obvious that methods must be devised and previous ideas of medical care adjusted, we must not lose sight of the fact that social needs today are more extreme than we anticipate for the future. It is our duty to mobilize the best current scientific knowledge for the benefit of the individual in the community.

The public is unaware of the extraordinary amount of labor and time, with monetary outlay, which is required to equip men and women for medical service. I daresay the public knows little of the risks and uncertainties of practice and expense of maintaining proper facilities for their work. Do they ever think of their doctor losing his health and deprived of his income?

The average physician is confronted with an economic problem which makes the practice of medicine precarious. It is clearly the duty of organized medicine to check the growth of community programs for medical service which undermine the financial stability of the individual physician. We concede the ideal that every family should have a hundred per cent of medical service. We recognize that families with annual incomes of under twelve hundred dollars receive but approximately thirty-three and one-third per cent needed health care and while those with salaries of greater amount receive correspondingly more medical service, it will require cooperation of an enlightened citizenship with a willing profession to develop plans suitable to the needs of a given locality.

The recent Report on the High Costs of Medical Care is significant, for it is based upon certain concepts of society and functions of government. As a Nation we have been developing governmental control to meet social demands without

having a definite policy.

The Great War left its quota of disabled. It seemed both wise and just to care liberally for the casualties and there was no objection. Without establishing a definite policy to meet such conditions for the present and future Congress yielded to the demands of a group of citizens for broader concessions. From that time on, Hospitalization and Compensation, with many other far-reaching governmental services became not only the goal of those interested as individuals in receiving benefits, but social welfare forces

became enthused in finding a solution for a more liberal aid for all the people.

Accumulated data have clearly emphasized the importance of medicine as related to social needs. Such data clearly support our belief in our present educational standard. Everyone realizes that there can be no one answer applicable to the varied conditions, social and economic, because they change in different environments.

Schwitalla has said: "That paradox of adaptation lies perceptibly in this; that a measure of isolation spells a continuation of life; exaggerated adaptation means death." A biological truth to be remembered. Also he has said "The organism which adapts itself to its environment with restraint due to self-contained inertia, survives."

The statement has been made that the medical profession of this country has been denied valuable information which is being developed and which is out of harmony with the view expressed in the Minority Report of the High Costs of Medical Care and elaborated in our own Journals. I feel that we can deny this charge.

The reaction of the leaders of our organization to the Report has been very much the same, and if one cares to investigate, it would be found that the profession throughout the country has responded in a similar vein. There is nothing more natural than the desire of a great profession to resist change until it has had sufficient time to adjust its mind, if that time should be needed.

The impatience of some of the leaders engaged in social welfare work to hurry the profession to a decision, even going so far as to threaten us with a definite campaign of propaganda to influence the public is worth noting. I am one of those who believes that it is wise to utilize enough time to erystallize our opinion. The public should recognize that medical men are better able to solve medical questions than anyone else; and that lay-opinion however suggestive and valued it may be, lacks finality and that essence of true understanding of a doctor's relationship to his

Our organization then is striving through its leaders at Headquarters and elsewhere, to serve the public and the profession of medicine; first, by discussion of problems; second, by trial of suggested plans; thirdly, by searching for and

finding the truth and thus be able to crystallize the professional mind so that unity will prevail. We all recognize that until there is unity of spirit and desire among the members of the County Medical Societies, which are units of our organization, no plan however far-reaching and humanitarian in its aspects, can hope to live without the cooperation of the majority of men practicing in that locality.

Medicine of all the arts is the most exacting. It is a jealous master of the time, opportunity, and capacity of those devoted to its service.

In pursuit of the underlying sciences, the art has sometimes been neglected. It is also true that sequential knowledge, culminating in the larger field of sociology and psychology, has become known to an ever-widening circle of humanity.

To adjust the science and art of medicine, to the satisfaction of this educated and expectant mass of socially conscious people, will not be difficult when the members of our profession unify their desire to lead those minds which want to control and direct the practices of medical men.

Regardless of our numerous and valuable associations, doctors throughout this country should recognize their need for a strong and militant national medical organization. It is the only body which can truly claim the loyalty of every worthy praetitioner. It can concretely express the aspirations and purposes of every follower of Aescalapius who believes in the fundamental principles of ethical medicine.

The American Medical Association has won the respect of its members and informed society. It has been faithful to a trust. Let us give it our

unswerving allegiance.

Dignity and economic fairness, as well as conscientious scientific service, depends upon the unity of the medical profession. Ethical standards have held. We have remained true to an ideal. Every appreciative man within our profession realizes his obligations to those who have left a wonderful heritage.

If this organization of ours should fail, medicine as we know it, would disintegrate; and if this should ever come to pass my friends, who would suffer more than the people who have learned to respect and trust us?

TONSILLECTOMY IN THE PRESENCE OF THYROID DISEASE

By H. GRIFFIN BULLWINKEL, M.D., NEW YORK, N. Y.

Read before the Section of Otolaryngology of the New York Academy of Medicine, May 18, 1932.

GREAT many papers presented at medical meetings deal with the more unusual and bizarre conditions met with in medical and surgical practice. It is the purpose of the writer of this paper to present a fairly common condition

which is met with not infrequently and which at times is given too little thought, namely: tonsillectomy in the presence of thyroid disease.

We are all aware of the fact that infection of the naso-pharynx may be an etiological factor in thyroid pathology. In fact, the writer just recently in private practice had a patient who presented himself with sudden and considerable enlargement of the thyroid which was limited to the isthmus alone. This was coincidental with a moderately severe pan-sinusitis. The patient's attention, however, was drawn to the thyroid enlargement and he was more concerned with it than he was with the infection in the nose and sinuses. Needless to say, within a few days after treatment was given the sinuses, the thyroid condition subsided.

Those of us who have done much tonsil work have seen many times thyroid pathology of different types improved after the removal of the tonsils. The writer has personally questioned many of the outstanding laryngologists in the city and they have all felt that tonsillectomy is, by and large, indicated in thyroid disease.

Many authorities, in their reports on thyroid disease state that it is usually advisable to remove the tonsils along with other foci of infection before thyroid surgery is undertaken.

The writer had always concurred in this belief until two cases on whom he performed tonsillectomies, developed subsequently thereto an acute thyroiditis. Only this past winter a case was reported at the New York Polyclinic Hospital of an acute thyroiditis following electro-coagulation of the tonsils. In a personal communication with the writer, Dr. Luther MacKenzie, of Bellevue Hospital, reports a fatal case of acute thyroiditis following tonsillectomy.

Case 1, Female, F. E., Age 22. The patient was referred to me for tonsillectomy and gave a history of having had frequent attacks of acute tonsilitis and about six months previously a severe peri-tonsilar abscess.

Upon examination, the tonsils appeared to be definitely diseased. Her entire physical examination was negative, except for the presence of a slightly enlarged thyroid gland. This was felt to be what is often called an adolescent type of goitre. Her pulse rate was 68, her metabolism—14 and she was at least 40 pounds overweight. Clinically, she appeared to be more of the myxædematous rather than the hyper-thyroid type.

A tonsillectomy was performed at 2 p.m. at the clinic of the University and Bellevue Hospital Medical College and was quickly and easily carried out. After the patient reacted from the anesthesia a quarter of a grain of morphine was given. This seemed to excite her, but when three and a half or four hours had elapsed, another quarter was given. This also excited her rather than acting as a sedative.

She had an extremely nervous night, and the nurse called me in to see her at 7 a.m., when I

found, much to my surprise, that her thyroid gland had increased two or three times its previous size. She had also developed some exophthalmos and all of the signs and symptoms of thyrotoxicosis. This condition persisted throughout her convalescence though it abated somewhat in its intensity.

She was taken to Roosevelt Hospital where several metabolism tests were taken which ranged from +50 to +60. After prolonged study a subtotal thyroidectomy was performed by Dr. Henry Cave. The patient today is well and has since become the mother of two children.

The second case I have to report is a sister of case 1, (E. W.).

She was of a decidedly different type, having clinical signs and symptoms of hyperthyroidism, with a metabolism of +30. She had had several attacks of acute tonsilitis and with each of these attacks the symptoms of thyroidtoxicity increased.

She was advised to have her tonsils out by her own physician. Before removing them, however, I had her confined in the hospital about a week for observation and rest. Having had a disagreeable experience with her sister, as reported above, I sought and received the advice of several other laryngologists. They all felt that the removal of her tonsils was indicated and that undoubtedly her thyroid condition would improve thereafter.

Her metabolism having dropped to +18, I removed her tonsils. She developed the same reaction that her sister did though not to as alarming a degree. She eventually recovered, though she still has mild symptoms of hyperthyroidism. She was living in the West when I last heard from her and is apparently greatly improved.

The question naturally arises as to the cause of the sudden thyroiditis following tonsillectomy. It has been suggested that perhaps the vascular and lymphatic channels transmit infection from the pharynx to the thyroid and also that the shock of operation upsets the balance of the central and sympathetic nervous symptoms thereby producing the thyroid crisis. The writer rather leans to the second of these two theories although both together may play some part.

These cases are not reported to prove or disprove any stated theories, but simply as a warning to all of us to be aware of this condition when we meet it.

My own opinion is that, by and large, attention should be given to the thyroid disease first and to the tonsils second, for it is certainly possible to precipitate an acute thyroid crisis by surgical procedures unless extreme care and thought are used.

Volume 33 629 Number 10

FURTHER RESULTS OBTAINED WITH THE RABBIT OVULATION TEST AS A DIAGNOSTIC PROCEDURE

By KARL M. WILSON, M.D., AND GEORGE W. CORNER, M.D., ROCHESTER, N. Y.

From the Department of Obstetrics and Gynecology and the Department of Anatomy of the University of Rochester, Rochester, N. Y. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

NE year ago we presented the results obtained with the rabbit ovulation test as originated by Friedman. In that first series of observations we investigated the results obtained in a series of normal pregnancies at various stages, as well as a number of abnormal pregnancies, and a variety of other conditions associated with abnormalities in the female pelvic organs. Our object in that study was to assess the value of the procedure as a diagnostic aid, and to learn the possible sources of error. Having found it to be of very distinct value in diagnosis, particularly in the diagnosis of early pregnancy which might otherwise not have been possible, we have continued its use and the present report presents the results obtained in a second series of patients in whom we made use of this procedure as a diagnostic aid.

Although the technique we have employed differs somewhat from that employed by Friedman and Lapham and by Schneider, particularly in the shorter time elapsing between the injection of the urine into the rabbit and the inspection of the ovaries at operation, our results have shown a high percentage of accuracy and they compare favorably with the results obtained with the original Aschheim-Zondek reaction. Furthermore, if the proper diagnosis is arrived at in a shorter time, it often proves to be of distinct advantage.

The technique as employed by us may be briefly repeated here. The procedure is based on the fact that ovulation in the rabbit is not spontaneous as in most other mammals, but ordinarily occurs only after copulation, though ovulation can be brought about by the injection of the gonad-stimulating hormones of the anterior pituitary body. The urine of pregnant women after about the third week contains large quantities of hormones resembling in their effects those originating in the anterior pituitary body, and as originally suggested by Friedman, such urine injected into a female rabbit will induce ovulation. We use only mature female rabbits, of no particular breed, which have been kept in strict isolation for at least a month. The test is carried out by injecting, without sterile precautions, 5 c.c. of the urine to be tested, into the ear vein of the rabbit. For the sake of convenience this is usually done about 5:00 P.M. in the afternoon. The following morning, that is approximately sixteen hours later, under ether anaesthesia and employing aseptic technique, the abdomen is opened and the ovaries inspected. If evidence of ovulation is discovered with recently ruptured Graafian follicles present, the result is considered positive, while if no evidence of actual

rupture of follicles is to be noted, the result is regarded as negative. The ruptured follicles at this stage will be very small, 1 to 2 m.m. in diameter, will be bright red in color, with a tiny umbilicated depression in the center. To the inexperienced confusion may be caused by the presence of rather large unruptured follicles, particularly if their vessels are injected, and also by the rather frequently found hemorrhagic unruptured follicles, dull red in color or almost black. These latter appear to be more or less peculiar to the rabbit. At present, the only modification of this technique that we would suggest is that on account of the fact that the reaction of the ovaries is occasionally delayed, it may at times prove advantageous to inject two animals at the same time. If the first one is found to show a positive reaction at exploration, nothing further is done to the second, while if the result is negative, the second rabbit may be explored twelve to eighteen hours later. In this way no unnecessary time will be lost in arriving at the result of the test. Very occasionally it will be found that the urine is of such a toxic nature as to cause the death of the animal within a short time after injection. If so the procedure will have to be repeated, using a fresh specimen. This is an infrequent occurrence, however, and only occurred on three occasions in our series. This difficulty may also be overcome by alcohol extraction, following which a larger dosage should be used for injection, a dosage comparable to 25 c.c. of the original urine, as some of the hormone is destroyed by alcohol.

While this procedure is of value at times in helping to exclude the possibility of the presence of a pregnancy, its chief value will be in the aid it offers in establishing a definite diagnosis of pregnancy. It has proved to be of particular value in early pregnancies where the findings on examination are not sufficiently marked to permit of a diagnosis being made, as well as in those pregnancies associated with complicating abnormalities which may render diagnosis difficult

PRESENTATION OF RESULTS

Observations were made on sixty-four normal pregnancies at various stages of pregnancy. In each instance the results were confirmed by subsequent observation of the patients studied. In estimating the duration of the early pregnancies, we have relied on the menstrual history and the lack of physical signs on examination. Those we have recorded as being three to four weeks pregnant were from seven to fourteen days past

their menstrual date. The results obtained may be tabulated as follows:

Twenty-seven observations were made on various types of abnormal pregnancy. These proved of value from the diagnostic standpoint and also served to emphasize certain important points to be kept in mind at all times in interpreting the results obtained with this procedure. They may be tabulated as follows:

The varying positive and negative results obtained are of interest according to the type of pregnancy with which we are dealing. They correspond to the findings we previously reported and they serve to confirm the statement we made in our first report, that the reaction can only be positive when active living fœtal tissue is in biologic contact with the maternal blood, or only very recently (not over 72 hours) separated from it. Thus in the incomplete abortions and ectopic pregnancies giving a negative reaction no active living fœtal tissue was found, while in those giving a positive reaction microscopic examination revealed living fœtal tissue to be present. In the missed abortions the ovum was still attached to the uterus, but microscopic examination showed the placenta to be entirely infarcted and no living feetal tissue could be demonstrated. Further observations may inform us how soon after the death of the ovum, but while it is still attached to the uterus, the reaction becomes negative. At present we cannot make any specific statement in regard to this.

This procedure was resorted to in sixty women who presented various menstrual disturbances. In each instance the history and findings were such as to at least suggest the possibility of a pregnancy either intra or extra uterine being present. In each instance the reaction was negative and in each instance subsequent observation revealed the fact that no pregnancy existed. The results in this group may be tabulated as

follows:

Functional amenorrhoa	24	cases	all	negative
Lactation "			"	a a
Menopause "	5	"	"	4
Irregular bleeding, not pregnant	10	"	"	"
Pelvic inflammation with irregular				
bleeding, not pregnant	19	61	"	- 11

In a group of twenty-one women presenting various abnormalities and in whom there was a possibility of an associated pregnancy the result was consistently negative and later observation proved no pregnancy to exist. Nineteen observations have been discarded from consideration on account of lack of subsequent observation. All of these gave negative results. The results in this miscellaneous group are as follows:

We had the opportunity of observing one instance of a chorio-epithelioma. This patient was included in our first series at the time she was under treatment for a hydatid mole. This patient proved to be of particular interest, and the course of events may be briefly outlined as follows:

Hydatid mole removed May, 1930.

One month later bleeding—curettage. Microscopic fragments of mole obtained, test positive.

July, 1930—bleeding—curettage. Normal endometrium, test negative.

Menstruated normally for a year.

August 26, 1931—bleeding—curettage, normal endometrium.

October 8, 1931—eight days past period, test negative.

October 21, 1931—menstruated normally.

December 26, 1931—admitted with cough and bloody sputum.

Small mass in anterior vaginal wall, uterus somewhat enlarged.

Ovulation test positive.

Died December 30, 1931—autopsy—chorio-

epithelioma.

This patient must have harbored living, though inactive fœtal cells ever since the expulsion of the mole, but they evidently did not produce sufficient hormone to give a positive reaction. At the time of her last admission, the growth was far advanced with extensive local involvement and extension to the lungs. While the test was positive at this time, yet nine weeks previous it had been negative, at a time when no symptoms or physical findings suggested the presence of a malignant growth. The result in this single case casts some doubt on the value of this procedure in the early diagnosis of chorio-epithelioma.

In five instances the procedure gave a negative result in spite of the fact that pregnancy was definitely present at the time the test was carried out. In three of them the reaction became positive in from five to fourteen days later. One was not seen again for two months when the reaction was found to be positive, while in

the fifth it was not repeated. It is interesting to note that two of these errors occurred in different pregnancies in the same woman. errors in the series may be tabulated as follows:

negative [7 days past menstrual period 2 weeks later positive $2 \left. \begin{cases} \text{Lactation 2 months ? pregnant} \\ \text{13 days later} \end{cases} \right.$ negative positive $3 \begin{cases} 2\frac{1}{2} & \text{months pregnant} \\ 2 & \text{months later} \end{cases}$ negative positive Same patient as m (2)

negative positive 10 days past menstrual period negative 5 { Test not repeated but later proven

definitely pregnant

These errors are of great importance in interpreting the results obtained from this procedure and indicate that this is not an infallible test. The failures probably result from a delay in the appearance of the hormones in the urine in sufficient concentration to cause ovulation in the rabbit. The cause for this delay is at present unknown In our first series we encountered three such errors in early pregnancy, the urine at first giving a negative reaction, while later

became positive. In our two series of observations we have studied 155 definitely pregnant, normal women, and have encountered in all eight erroneous negative results-an accuracy of approximately 95%, while if the other conditions studied are added to this, that is those cases where a correct negative result was obtained, the percentage of error is found to be considerably lower. This compares very favorably with the results obtained by the original Aschheim-Zondek reaction.

In this series the only positive result obtained in the absence of pregnancy was in the single case of chorio-epithelioma, a fœtal cell tumor. In our first series we found one positive reaction in a non-pregnant woman who presented a marked degree of endometrial hyperplasia.

SUMMARY AND CONCLUSIONS

The results obtained in 198 observations in which the rabbit ovulation test was used as a diagnostic aid are herewith presented. In our experience it has proved to be of great accuracy. The results are fully comparable to the Aschheim-Zondek reaction, and it has the added advantage of requiring much less time for its de-A positive reaction almost intermination variably indicates that active feetal tissue is in biologie relationship with the maternal blood stream, or has been very recently (not over 72 hours) separated from it. Such errors as occur are most likely to be on the negative side. It must be kept in mind that a negative result does not always exclude the possibility of pregnancy, but may be due to the fact that the ovum has perished some time previously (either intra or extra uterine), or that in an occasional normal pregnancy the appearance of the hormones responsible for the reaction in the urine is delayed. A negative result, however, is often of value in helping to exclude the possibility of pregnancy

DISCUSSION OF OVULATION TEST ON RABBITS By A CHARLES POSNER, M.D.

Since March 3, 1931, we have used rabbits for Ovulation studies at the Harlem Hospital, New York

We have made 525 tests, and have never found a false positive. We have had 10 cases which were false negatives giving us a percentage of

accuracy of 98%

On checking over these ten false negative cases, we found that there was a failure to follow the requirements of the test, such as (1) the pa-tient had been taking some drug, or (2) the specirequirements of the test, such as men was not a morning one, or, (3) the bottle was unclean and had previously contained some chemical Not only have we been able to produce this test with nrine, but with blood serum and animotic fluid

We have been unable to produce positive tests with spinal fluids or with colostrum

In two cases we have been able to establish the diagnosis of pregnancy before the patients had anssed their periods. In one case it was 9 days after the last regular menstrual period, and further study of this patient proved that she was pregnant. In the other case it was 8 days after a known exposure, the patient having been delivered of a child one month before, and further studies confirmed the diagnosis of pregnancy

We have found this test to be of great value in the diagnosis of pregnancy, either literine or ectopie, and it remains so for 48 hours after dehvery. We have found it to be present in 2 cases of hydatidiform mole, and it is in these cases we have found it to remain positive the longest time—8 days after the expulsion of the mole. We have tried to study the urine of these patients, who have had hydatidiform moles, weekly after their discharge from the hospital in order to detect, without delay, chorioepithelioma, should it develop

The way we differentiate between normal preg-

nancy and hydatidiform mole is by diluting the urine 1 to 100 with saline. It will be positive in hydatidiform mole and negative in pregnancy. This was done in one of our cases. We have had no cases of chorioepithelioma in the female, but we have been able to exclude a suspected case by repeated negative tests. This was finally proved to be malignant leiomyoma.

In all male patients who have tumors of the testicles, or who have had previous operations in which their testicles have been removed, we have performed this test; in one we have had a positive result. This was a man who had an operation for the removal of his testicles 5 years ago and had developed a large mass in the abdomen. The test was positive and further study of the case showed the presence of chorioepitheliomic tissue. We feel that the test has some relation

to the chorionic tissue as well as to the pituitary gland.

We have found it to be negative in tubal abortion and to remain positive for 36 hours in incomplete abortions.

I wish to call the attention to the members of the Society to two particular points: (1) Beware of deception and substitution of the urine as we have had substitute urines given us by women who wished to conceal their pregnancies, and (2) there must be no drugs either in the patient or the bottle at the time of specimen is obtained.

I wish to congratulate Dr. Wilson and agree with him on the advantages which the rabbit test has over the use of mice, and I have found it to be easier to interpret, as accurate as, and quicker than, the mouse test.

RINGWORM OF THE TOES IN STUDENTS AND DISPENSARY PATIENTS By EMANUEL MUSKATBLIT, M.D., NEW YORK, N. Y.

From the Department of Dermatology and Syphilology, University and Bellevue Hospital Medical College, Service of Dr. Howard Fox. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

TNTERDIGITAL mycoses of the feet occupy a most important place among fungous diseases of the skin and their increased incidence has been noted by many observers during recent years. It is difficult to say whether these cases have really become more frequent or whether they attract more attention than before. Toe ringworm often appears as a very inconspicuous lesion without marked subjective symptoms. It can, however, assume an acute inflammatory character, cause severe itching or pain and even impair the The process may involve the general health. soles, the dorsal and lateral aspects of the feet and other parts of the body favorable for fungi such as the groins, intergluteal folds, axillae and umbilicus. Toe-webs may thus become a reservoir where pathogenic fungi remain for a long time even for years and from which they spread over the skin. Furthermore fungous toxins absorbed from the lesions on the feet may influence the entire organism and cause a general allergic hypersensitiveness of the skin to fungi and their In such cases fungous material from the primary foci carried into the skin by means of hematogenous transport may cause secondary eruptions (dermatophytids). Their nature is difficult to determine as they are sometimes of purely toxic origin or because the organized fungous elements producing them are rapidly destroyed and cannot be found by either microscope or culture.

The present survey is based on the study of two groups of persons: (1) 100 patients from the skin clinic of the University and Bellevue Hospital Medical College and (2) 112 medical students. In order to determine the relative incidence of interdigital mycoses all of these 212 persons have been taken for examination without choice, regardless of their complaints or objective

changes in the skin. The group of students can evidently be considered to be of a higher cultural

level than dispensary patients.

After a brief description of the skin conditions, scrapings were taken from all toe-webs whether abnormal or not and also from other skin lesions it present. Preparations made in 30% KOH solution and left for one to two hours under the coverglass were then heated to the boiling point and examined. If fungi were found their microscopic appearance was described. Cultures were planted from every case, regardless of the result of the microscopic examination, on Sabouraud's isolation medium using French glucose and peptone. Three to four culture tubes with six to eight scales in each were planted from every case. From 12 to 16 tubes were seeded when disseminated lesions were present, the material being taken from separate areas. When cultures in spite of positive microscopic results, were negative, the remainder of the scrapings was planted again and thus the culture of pathogenic fungus was at times ob-Culture tubes left at room temperature and in the light were observed for several weeks. From colonies suggesting a pathogenic type, transplantations were immediately made into fresh tubes or Erlenmeyer's flasks on the same medium and also on Sabouraud's conservation medium. The classification of species was based on their external appearance on both media and on their form of growth and sporulation, studied by means of direct observation of a culture tube under the microscope and examination of a piece of culture in a drop of water or alcohol. If necessary hanging drop cultures were made.

Table I shows the incidence of these changes of the skin in the toe-webs which looked clinically suspicious from the standpoint of mycotic infec-

tion. Such cases are designated "clinically positive."

	ΛT	BLE !	Į.			
Clinically positive Clinically negative	Dispen- sary 85 15	Per cent 85	Stu- dents 103 9	Per cent 91.9	Total 188 24	Per cent 88.7
TOTAL	100		112		212	

Thus in 188 from 212 persons examined (almost 89 per cent) such changes were present. The percentage in students is a little higher than in dispensary patients (92 against 85). Included as "clinically positive" were cases with mild changes of the skin for not infrequently pathogenic fungiare found in lesions without typical clinical features (slight maceration or scaling). Although perfectly normal skin occurs rarely in the tocwebs it would be improper to consider toe-ringworm a "universal" disease as many other causes besides fungi may cause similar changes such as

Figure 1

Filamentous fungus in toc-web scrapings, Potassium hydroxide. (Courtesy of Dr. Howard Fox.)

bacterial infections, friction, decomposition of the sweat with formation of irritating chemical products, etc. The exact diagnosis of a mycotic process in the toc-webs requires in my opinion, microscopic examination and cultures. The mere presence of mycosis-like clinical changes is insufficient. In 15 per cent of fect examined all interdigital folds were involved and in 85 per cent only a part of them, most often the fourth (97 per cent) and least often the first (19 per cent).

In some cases the process was simple: there was only maceration or hyperkeratosis or dry scaling, in others we found a combination of various changes. Macerated epidermis was most frequently the main feature with which hyper-

keratosis, bullae, fissures and crosions were assoeiated. Dry lesions whether hyperkeratotic, squamous or erythemato-squamons were relatively rare. Patients were observed where the process on buth feet differed, such as maceration on me foot, er lesions of hyperker he other and also case he same foot showed various changes, maceration in some, sealing or lyperkeratosis in others.

Microscopic findings—Preparations designated "microscopically positive" were those showing typical mycelia of filamentous fungi (Hyphomycetes) or "yeast-like" fungi. In hyphomycetes (Figure I) one sees mycelial filaments of various lengths, widths and shapes. Thin threads correspond to the young stage of the parasite. They

Culture of epidermophyton interdigitale from toe-webs.

are usually straight, of regular diameter, seldom branch, their septa are few and not very marked. Older elements are thicker, more irregular. curved, branch frequently and possess numerous and noticcable septa. In its further development a thread breaks down into a chain of separated segments (spores) which may have different size and shape and be globular, ovoid, cylindrical, cubical or quite irregular. Some of them germinate and give off sprouts which grow into a typical mycelial filament. Threads and chains may form bunches or a more or less dense network. We find also single dispersed spores and groups of them originating partly from the natural process of breaking down of chains partly from the technic of preparation. In true hyphomycetes they are however, not so prominent in comparison

with threads and chains which constitute the main mass of the parasite. A different microscopic picture is seen in preparations with "yeast-like" fungi, namely groups of closely packed yeast-like cells roundish, oval or elongated, some of which are budding. Mycelial filaments may be entirely absent or few and rudimentary. In some cases, however, they are numerous, well developed and form chains. Budding spores are also present on the hyphae themselves

Table II shows microscopic findings.

Tabi e II						
	Dispen-	Per cent	Stu dents	Per cent	Total	Per cent
Microscopically positive Microscopically negative	27 73	27.0	32 80	2 8 6	59 153	278
TOTAL	100	•	112	•	212	

The percentage of microscopically positive cases in both groups was almost equal, in students a little higher than in dispensary patients (286 against 27.0) and the average for all 212 examined persons was 27.8.

FIGURE 3
Culture of epidermophyton inguinale from toe-webs.

Table III gives the subdivision of fungi as seen under the microscope into the two mentioned types.

• •	TABLE II	I	
	Dispensary	Students	Total
Filamentous	20	23	43
Yeast-like	7	9	16
TOTAL	27	32	59

In approximately 75 per cent filamentous fungi were found microscopically and in 25 per cent

yeast-like organisms were present.

It is well known that microscopic examination for fungi even in clinically typical cases by no means always gives positive results, particularly when the glabrous skin or nails are involved. The relation between clinical and microscopic findings is shown in the Table IV.

		Тлы	E IV		
		Miero- scopically	Micro scopically	Mı	Per cent croscopically

TOT	AL	59	153	212	278

Figure 4
Culture of epidermophyton rubrum from toe-webs

Of 188 clinically positive cases, 59 (31.4 per cent) were also microscopically positive. The chances of finding fungi are much greater where skin lesions are more pronounced. Of 78 cases with marked lesions in the toe-webs 37 (47.4 per cent) were positive under the microscope while of 110 with mild symptoms in only 22 (200 per cent) were fungi found.

Cultures were positive in 38 of 212 (17.9 per cent), Table V showing species of fungi grown

from toe-web scrapings.

	TABL			Total

Monilia		3	Ų,	3
Cryptococcus		0	3	
			22	38
TOTAL		15	23	20

The first four species—Epidermophyton and Trichophyton belong to those hyphomycetes whose pathogenic importance is definitely established, while the last three yeast-like fungi Oidium, Monilia and Cryptococcus are frequently considered as saprophytes and accidental contaminants of the skin. Clinical observations, however, together with experiments in animals and men have

proved that these fungi may also become pathogenic. They have therefore been considered but only in cases where they grew in several culture tubes from all or almost all seeded particles and where the result of cultures corresponded to the microscopic appearance. It is assumed therefore

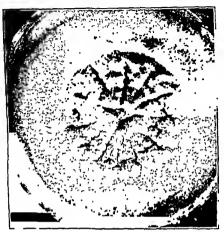

Figure 5
Culture of trichophyton gypscum from toe-webs.

that among these cases there were interdigital superficial eryptococcosis, oldiomycosis and moniliasis. In general, of 212 persons examined regardless of their history, subjective symptoms or objective appearance of the skin, 38 (17.9 per cent) proved to be carriers of pathogenic fungi in their toe-webs as shown by cultures.

Table VI shows the relation between the micro-

scopic and cultural findings.

TABLE VI

Microscopically positive Microscopically negative		Cultures negalive 20 145	Total 59 153	Per cent of positive cultures 50 8 5.2
TOTAL	38	174	212	17.9

Of 59 microscopically positive cases, 30 (50.8 per cent) were also positive culturally. This result should be considered very satisfactory because of known fact that cultures are not always positive when the microscopic preparation contains fungi. The causes of this might be:

(1) Material taken for planting occasionally does not contain any fungi.

(2) Fungi are present in the scrapings but will not grow on artificial culture media.

(3) Pathogenic species are overgrown in cultures by saprophytes.

Of 153 microscopically negative cases only 8 (5.2 per cent) gave positive cultures (one dispensary patient and seven students). All of them were clinically positive. A negative microscopic examination, therefore, predetermines almost surely a negative culture though in a small nercentage of cases it was possible to prove the mycotic origin of skin lesions by cultures where the microscope failed. Adding 8 cases proved only culturally to 59 which were microscopically positive, gives 67 patients with toe-ringworm out of 212 persons examined (31.6 per cent). The dispensary group gave 28 cases (28.0 per cent) and students 39 (34.8 per cent). It is worth noting that the incidence of toe-ringworm was higher in students despite their better hygienic conditions than in dispensary patients.

Among the species of fungi isolated from our material one predominated, namely Epidermophyton interdigitale (also called Trichophyton interdigitale) which was found in 19 cases. This fungus belongs to the most common pathogenic types in this country and occupies the first place not

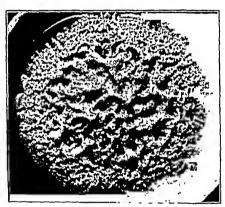

FIGURE 6
Culture of oidium rotundatum from toe-webs.

only in toe-ringworm but also in other mycotic lesions of the glabrous skin throughout the material of our clinic. It possesses an extraordinary viability and energy of growth resisting successfully in culture tubes such saprophytes as Aspergillus or Penicillium. Its cultures from our interdigital cases were rather uniform and characteristic. The culture (Figure 2) starts as a white fluffy point, grows fast and forms a flat disk with creamy-yellowish slightly powdery central area and white, downy and elevated border. Pleomorphic degeneration develops as a rule very soon. Microscopically the culture shows a very abundant sporulation in the form of (1) long hyphae

bearing numerous lateral spores, (2) dense treelike branchings covered with similar spores (grapes) and (3) some multilocular spindlespores. In addition corkscrewlike twisted hyphae (spirals) are usually present in abundance.

Epidermophyton inguinale (Figure 3) in these two cases grew typically and very slowly, forming yellowish greenish, powdery cultures with irregularly convoluted surface and great tendency to pleomorphic degeneration. Microscopically in the culture only one type of spores could be found,

namely multilocular spindles.

Cultures of Epidermophyton rubrum (Figure 4) were at first white and downy, later the basis of the culture developed dark red pigmentation which also stained the adjacent part of the medium. The cultures rapidly became pleomorphic. Microscopically the picture resembled Epidermophyton interdigitale with the same spore bearing hyphae, grapes and spindles, but spirals were absent.

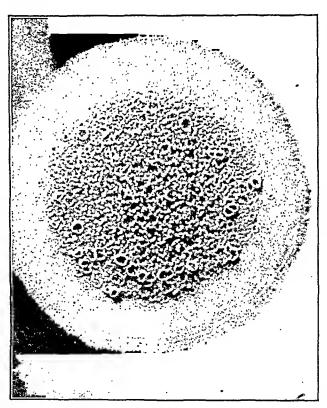

FIGURE 7
Culture of Monilia albicans from toe-webs.

Two cultures of Trichophyton gypseum (Figure 5) greatly resembled Epidermophyton interdigitale in external appearance and microscopic structure and a mistake in differentiation of these two species was quite possible. Because of some external properties like shape, coarse powder of the surface and numerous daughter-colonies I have classified these cultures as Trichophyton gypseum. In the absence of animal experiments,

however, I could not state the biological properties of these fungi, mainly their relation to the hairs (the latter being invaded by Trichophyton gypseum which is not the case in Epidermophyton interdigitale). Thus it is possible that these two strains classified as Trichophyton gypseum belong in fact to the gypseum-like variety of Epidermophyton interdigitale.

Cultures of Oidium (Figure 6) were all of the same type being brownish with a moist glossy and convoluted surface (Oidium rotundatum Castellani). Under the microscope were seen masses of yeast-like cells, some of them budding and also abundant septate mycelium, solid in the early stages of development, later breaking down in chains of segments (oidia or arthrospores).

Monilia (Figure 7) grew in our cases as creamy-white moist and glossy yeast-like cultures whose central area later formed numerous tiny folds, convolutions, and depressions. The periphery was flat or showed shallow radial grooves. Monilia has a tendency to grow deeply into the medium and older colonies particularly in the upper part of the culture tube where they soon begin to dry and produce at their border a characteristic halo made up of numerous long branching mycelial filaments, penetrating far into the medium. Microscopic study of Monilia cultures shows masses of yeast-like cells, many of them budding, and typical mycelium, whose hyphae consist of elongated segments with tree-like branching and bear numerous yeast-like budding spores. The latter appear at first in groups but in old colonies they form dense masses surrounding the hyphae like a sheath. Stab cultures in tubes with solidified gelatin are of great value in identification of Monilia and in its differentiation from simple yeasts. Monilia grows abundantly within the medium even 6-8 c.m. beneath the surface along the line of the "stab" in the form of radial mycelial filaments. Fermentation tests with 1 per cent peptone-sugar-waters with various carbohydrates show production of gas mostly in the presence of dextrose, at times also in levulose, maltose and saccharose.

The last three yeast-like cultures reported were flat creamy-white pasty with slightly darker central area. Neither mycelia nor ascospores could be found even in very old cultures. We believe therefore that these fungi could be classified as "cryptococcus."

Cases of Toe-ringworm associated with other Fungous Emptions

Two patients (101, 181) also had typical onychomycosis of the feet. Mycelium was found in scrapings from the nails and toe-webs.

Case 68 presented a macerative interdigital process and also a vesicular eruption on both soles and right hand (palm and palmar surfaces of the fingers). Scrapings from toe-webs, soles and hand contained mycelia. Cultures from all lesions showed epidermophyton interdigitale. This case is interesting as a true mycosis of the hand which is much rarer than one affecting the feet.

Case 48 presented as erythemato-vesicular patch on the right foot occupying its dorsal surface and toe-webs. A similar eruption was present in the fold between the index and middle fingers of the right hand. Scrapings from both foot and hand showed numerous yeast-like eells, some of them budding. This case may be eon-sidered as superficial blastomycosis. Clinically the lesion on the hand corresponded to the initial stage of the Erosio interdigitalis blastomycetica.

Case 74 resembled the foregoing one but was more extensive. There were present maceration in the toe-webs and dorsal surface of both fect, vesicular eruption on both soles and palms, crythemato-squamous and vesicular moderately infiltrated patches, some with well defined border on both legs. Yeasts were found microscopically in all lesions. This was possibly a generalized superficial yeast infection of the skin originating from inter-

digital blastomycosis of the feet.

Case 64 was still more extensive. There was a macerative process in the toe-webs of both feet. On the trunk and all extremities were numerous erythemato-squamous plaques. That on the left leg which appeared first was slightly infiltrated and covered with vesicles and crusts. Scrapings from both toe-webs and trunk contained yeastlike cells partly growing into mycelial filaments. Cul-tures which were positive only from the toe-webs showed Oldium. Assuming that this fungus was really pathogenic one must consider this case to be an interdigital oidiomy cosis complicated by a generalized eruption due to the same parasite.

Case 80. There were marked interdigital maceration

and erosions on the feet with vesicles and bullae on both soles. On the chest, abdomen, back and thighs there were numerous circinate patches, 1-5 c.m. in diameter with well-defined border. The periphery slowed an erythema and crusts from dried out vesicles and the center regressive changes with brownish pigmentation. Microscopically yeast-like fungi with budding cells and my celial filaments were present in the scrapings from toe-webs, soles and trunk, Lesions on the trunk were culturally negative. Material from interdigital folds of each foot was planted separately in three tubes with seven scales in each. From the right foot 12 pure cultures of Monilia were obtained. From the left foot the result was still more definite. All 21 seeded particles gave pure monilia cultures. Scrapings from one sole showed only the marginal strain of infection by though it was by each fungus ill the pathogenesis of this case.

Cases of Toe-ringworm accompanied by possible Dermatophytids

 The following six patients suffering from toe-ringworm proven microscopically or culturally also presented emp-tion on other parts of the body which were negative for fungi and might possibly be interpreted as dermatophytids.

Case 29. Maceration in the toe-webs. Cultures showed Epidermophyton interdigitale. On the left hand there were erythemato-vesiculo-squamous lesions which were

negative for fungi.
Case 114. Dry scaling in the toe-webs with remnants of vesicles on the feet. Cultures from both locations showed Epidermophyton interdigitale. On both palms and in the finger-webs there were redness and scaling,

negative microscopically and in cultures.

Case 81. Macerative interdigital mycosis of the feet with Trichophyton gypseum in cultures. On the chest, back, abdomen, upper extremities and thighs there were numerous erythemato-squamous patches from one to three cm. in diameter, partly of circinate type with well defined active, slightly infiltrated border and scally brownish pigmented centre. The generalized eruption which was negative for fungi was possibly of hemato-genous origin and could be considered as a dermato-

phytid, more exactly a trichophytid due to Trichophyton

gypseum localized in the toc-webs.

Case 100. Macerative interdigital lesions on the feet. In four seeded culture tubes 26 pure monilia colonies were grown. In the meantime diffuse erythema and scaling on both palms and lateral surface of the index and middle fingers of the right hand appeared which were negative for fungi. Case 72. Very marked process in the toe-webs. In

the scrapings yeast-like fungi were found with budding planted, 3 from each foot, all 37 particles giving pure cultures of Monilia. On both hands there was diffuse erythema and scaling involving the palms, dorsa of the hands and all the fingers. From the right hand the eruption spread over the forearm to the elbow. Microscopie and cultural examinations were negative. There was sufficient evidence to consider the last two cases interdigital moniliasis. The lesions on the hands were possibly secondary ones of allergic origin and could be considered as moniliids.

Case 121. Macerative interdigital mycosis on both feet with filamentous fungi in scrapings. Both soles, both palms and palmar surface of the fingers showed numer-ous round or polycyclic areas with scaly border due to the separation of the superficial horny layer. These lesions of the type Keratolysis exioliativa were negative for fungi and belonged possibly to the epidermo-

phytids.

Summary and Conclusions

(1) One hundred dispensary patients and one hundred and twelve medical students taken without any choice were examined for toe-ringworm, In 89 per cent of these 212 cases there were more or less pronounced changes of the skin in the toewebs, mostly of macerative type, suspicious from the standpoint of mycotic infection.

(2) Fungi were found microscopically or in cultures in 31.6 per cent of all cases examined. The percentage was higher in students (34.8)

than in dispensary patients (28.0).

(3) Microscopic examination alone was positive in 27.0 per cent of all cases. This percentage increased to 31.4 when clinical changes in the • skin were present and reached 47.4 in the group of patients with marked skin lesions. Two types of fungi could be distinguished in microscopical preparations. True hyphomycetes and yeast-like

(4) Cultures were positive in 17.9 per cent of all cases, in 50.8 per cent of microscopically positive cases and in 5.2 per cent of microscopically negative ones. No fungi were found either microscopically or culturally in clinically healthy

persons.

(5) Seven species of fungi were isolated from cases of toe-ringworm. The commonest organism was Epidermophyton interdigitale (19 from 38 cultures) and the following filamentous fungi in order of frequency were: Epidermophyton rubrum, Epidermophyton inguinale and Trichophyton gypseum. In addition yeast-like fungi Oidium, Monilia and Cryptococcus apparently played an important part as causative agents. Mixed infection with Epidermophyton interdigitale and Monilia is described.

INSULIN IN HYPOGLYCEMIA

By CHARLES B. F. GIBBS, M.D., ROCHESTER, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

NE is struck by the extreme variability of symptoms occurring in hypoglycemia. It soon becomes apparent that children and elderly diabetics must be most carefully watched, because at these extremes have seemed to occur the most bizarre reactions.

A test which the nurses have found of value in determining the proximity of a reaction in a child who is acting strangely after insulin dosage, has been to take the rectal temperature. If this is found below normal, orange juice is at once administered. Rectal temperatures of 96 have been observed.

All patients are instructed to carry wrapped squares of cane sugar and an identification card with instructions referable to the immediate treatment of insulin reaction.

Some of the severe diabetics are certainly far more comfortable if aglycosuria throughout the entire 24 hours is not demanded of them. In some instances I have been satisfied with sugarfree urine after 11 a. m. though the after-breakfast test was brick red. To eliminate these beforebreakfast and after-breakfast spills, requires the holding of glycogen during the long night period by an annoying additional injection of insulin or an early morning dose. Tolerance does not seem to be lost by allowing this morning excess.

In this matter of blood sugar levels it is well to stress the need of higher values with elderly patients having signs of arteriosclerotic coronary arteries. In the early days of insulin usage I am positive that my meticulous control of the diabetes in a woman of 60 years, led to rapidly increasing substernal distress and finally to sudden death from coronary occlusion. After months or years of adjustment to higher blood sugar levels, the heart muscle suffers from a relative sugar starvation when this level is again forced down to normal.

Strouse and his co-workers have recently reported some interesting experimental work on this type of patient and have demonstrated all the symptoms of angina even to the electrocardiographic changes, not only by insulin administration, but also by the use of low carbohydrate diets alone. This would suggest that the mechanism of what has been termed "insulin angina" depends on the insufficiency of available sugar rather than on insulin per se.

In view of the extensive, and in many instances, careless use of insulin at the present time, it seems remarkable that more fatalities have not occurred. Data is accumulating, however, which would indicate that larger doses do very little more to the individual than considerably smaller doses. That is, 100 units of insulin pro-

duce by no means 5 times the effect of 20 units. Apparently there is some mechanism available to modify the effects of insulin and so minimize harmful effects.

That hypoglycemic death may occur without the use of insulin artificially, has been demonstrated numerous times in the past few years.

A brief presentation of a case illustrating this condition may again emphasize the symptomatology and diagnostic possibilities. I am indebted to Doctor Stanley H. Erlenbach for the privilege of seeing this patient and reviewing the data.

Mrs. K. H., age 34 years, first seen March 17, 1930.

Chief Complaint: Sinking spells—periodically for 2 months.

Present Illness: For the past 2 months patient has had attacks of weakness which usually come on at 4 to 5 a. m. or 9 to 10 a. m. During these attacks she is very weak and extremely tired. She says she is too tired to move. At times she is dizzy at the beginning of these attacks. The attack lasts for several minutes to one-half hour after which the patient is irritable and wants to sleep. There is no cough or expectoration but the patient says she has lost 10 pounds in weight during the past few months. Appetite fair—bowels fairly regular. No edema.

Past History: Measles is the only childhood disease she remembers having had. Occasional cold. Tonsillitis—10 years ago. Operated at age of 17—one ovary and appendix removed. Menses 13x5x30—usually has severe headaches which end by vomiting at periods. Two normal pregnancies.

Family History: Husband and two children living and well. Father died at 38—appendicitis. Mother alive and well. Four sisters and two brothers all alive and well. No family history of migraine, T. B., cancer, diabetes, heart or kidney, disease to patient's knowledge.

Personal: Cares for her home. Considerable financial worries recently.

Physical Exam.: Weight 121 pounds. Height 5 feet 11 inches.

General Appearance: Well nourished and developed female 34 years of age who does not look ill. Ears—drums intact. Eyes—pupils are equal and react to light and accommodation. Fundi appear normal. Mouth—teeth in good condition. Tonsils small. Mucosa normal color. Neck—thyroid is small, soft and symmetrical. No adenopathy. Chest—Short, thick type of chest. The lungs are clear throughout. Heart—apex 5th. i.s. Not definitely located. No murmurs. Muscle sounds of good quality. B. P. 126/70. Periph-

Abdomen-liver and eral vessels feel soft. spleen not felt. There is generalized tenderness over the colon. Pelvic—Relaxed floor with torn cervix. Fundus good position. Extremities-No edema. Ankle and knee jerks obtained.

Laboratory Findings:

Urine-1015 acid, albumin none, sugar none, misc-few epith, cells.

RBC---4,460,000 Blood—Hgb. 90% Sahli. WBC 8.57

Basal

X-rays o appear at Proareirregular intervals and patient was admitted to the Strong Memorial Hospital for study, on June 9, 1930. During the stay in hospital had a convulsive scizure. WBC-18,000. Spinal Fluid Discharged June 30, examination-negative. 1930.

After leaving the hospital went to Buffalo where she consulted several physicians. Diagnosis of "neurasthenia" was made.

Returned to Rochester about September 1, 1930, after which time she had daily attacks of coma for short periods. These attacks were followed by crying and screaming. At one time patient had marked ataxia with incoordination of all movements and walked with a high steppage gait staggering as if intoxicated. Within 1 hour of this attack she was out walking up and down street with husband and said she felt "fine."

On night of September 3, 1930 patient went to bed as usual but in the morning was comatose and could not be aroused. Admitted to the Rochester General Hospital. Blood sugar found to be 17 mg. per 100 cc blood. Temperature ranged from 99.8 to 103.6 and at end of 2 weeks patient died with pneumonia, never regaining consciousness from time of admission until death. amounts of glucose were given I. V. Blood sugar increased to 97, 135, 130 and 82. Then recorded as 620 only to fall to 31 and 20 before death in spite of glucose administration.

Positive Findings: Variable neurological signs. At one time positive Babinski and ankle clonus on right side. Marked lateral nystagmus. Evidence of spastic paraplegia right arm and right leg. Marked restlessness.

Autobsy Findings: Pancreas normal size, shape, color and consistency. Near the tip of the tail, there is a small round tumor 13-7-10mm, which is of a pinker color than the surrounding tissue. It is easily shelled out of its bed. The right adrenal is larger than normal and of a deeper red color and on section shows a hemorrhagic cyst. Bilateral lobar pneumonia.

ARRESTED SHOULDERS IN VERTEX PRESENTATION By MARK HORNSTEIN, M.D., NEW YORK, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

THE primary problem of the obstetrician, in so far as the passage of the child through the birth canal is concerned, is that of overcoming obstacles to the delivery of the fetal head. The importance of emphasis upon this phase of obstetrics is justified, not only in the present state of our obstetrical knowledge: it will continue to constitute our chief preoccupation until such time as we have a definite understanding as to the nature of the numerous factors involved in the mechanism of parturition.

This statement may strengthen the general impression, that once the child's head has been born, mere expectancy, or perhaps slight traction on the head will bring the birth to completion. While fortunately, this is true in the vast majority of cases, not infrequently, the shoulders of the child become arrested after the head is delivered, and a constantly increasing number of instances present themselves in which it becomes exceedingly necessary to render special attention even after the head has been born. One of the reasons for this increase is undoubtedly due to the fact that more

frequent resort is made to forceps or anæs-The obstruction may occur either as a result of faulty position of the shoulders or because of their excessive breadth. There are different degrees of shoulder arrest ranging from a slight delay (when the patient is under anæsthesia and unable to bear down) to an extreme and rare degree of arrest which necessitates various operative procedures such as cleidotomy, decapitation, amputation at the shoulder joint and version.

One possible untoward result of prolonged delay due to shoulder arrest is death of the child from compression of the umbilical cord if the latter should be prolansed into the true Another danger is that of paralysis pelvis. of the Erb-Duchenne type if forcible traction is brought on the head in a faulty manner. If the head is pulled in a direction which causes the distance between the angle of the jaw and the corresponding shoulder to become increased, it is apt to result in permanent paralysis of the arm, due to the tearing of the lower cervical nerves. This latter occurrence is by no means rare, judging from the more than

frequent allusions to the subject made by orthopedic surgeons.

The text books describe various methods for dealing with this complication. In general, they consist of a series of attempts, which,

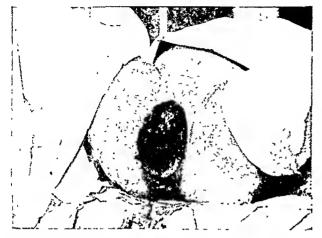

FIGURE 1. All of head but chin is born. Old unhealed perineal laceration in multipara; failure of head to advance due to shoulders arrested at superior strait.

from their variety alone, betray their doubtful value either in accomplishing the desired result, or in doing it without causing harm. Maternal bearing down efforts and manual pressure from above are comparatively safe, but of little or no value when the shoulders are, as is usually the case, arrested at or in the inlet of the pelvis.

When the shoulders are arrested at the pelvic inlet, it may be evidenced almost immediately after the caput presents by an otherwise unexplained slow advance of the head The head often reover the perineum. remains in the introitus long after its largest diameter has emerged from the pelvic outlet and when the soft parts no longer offer any resistance. Indeed, the child's chin may be the only part of the head remaining undelivered (Fig. 1). Even if the chin is extracted by sweeping a finger over the perineum, and extending the neck, the head remains tightly imbedded in the perineal soft parts on account of the relatively insufficient length of the neck. Restitution, therefore, does not take place, and the occiput remains under the pubic symphysis (Fig. 3).

In order to attempt delivery by the usual methods the accoucheur first rotates the head into restitution (Fig. 2) and then proceeds in his efforts by employing any one or a combination of the accepted methods. He usually succeeds in the delivery but sometimes this is accomplished at the risk or actual cost of injury to bone or nerves. The method of delivering arrested shoulders in vertex presentation hereby presented offers the advantages of freedom

from risk of injury and assurance of success in delivery.

TECHNIQUE

In left occiput anterior position the left hand of the operator is placed on the child's occiput. just left of the median line; the right hand steadies the chin, being placed just right of the median line (Fig. 3). The head is rotated slightly to the right of the symphysis pubis, contrarywise to restitution. Traction is applied to the head with the left hand; the direction of the pull being downward and to the right, always with the tendency of bringing the two hands of the operator, which, at the beginning of the maneuver, were partly crossed, into their normal relation to each other. The force of the pull thus passes through the outer fibres of the left trapezius muscle of the child onto the left or posterior shoulder. It is this shoulder which is soon made to point at the outlet (Fig. 4). To com-

FIGURE 2. The wrong method, consisting of restituting the head before pulling. Irrespective of which shoulder is pulled first, there is danger of brachial paralysis. The position is left occiput anterior.

plete the extraction one may continue pulling and deliver the same shoulder first, or the head may be returned to its original position, depressed and the right shoulder extracted first. In some cases of arrested shoulders restitution may not be interfered with, the child's neck being sufficiently long to rotate, or because the pelvic inlet is low or the patient is of slender build, factors which render a greater length of neck available and facilitate external rotation of the head. The procedure to be followed then is the same but the occiput must first be rotated to the right of the symphysis along a longer arc than in the usual instance, before traction is commenced. In posterior position of the occiput, with the head restituted, the occiput need not be brought around as far as the symphysis. It is enough to rotate the head for a sufficient distance to enable one to apply the traction so that the force passes along the outer fibres of the posterior trapezins muscle unto the left shoulder. When the position of the child in utero has not previously been ascertained, one may be guided by locating the position of the back digitally.

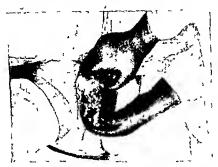

FIGURE 3. Some position. The chin hos been delivered by increasing extension of the hood. The lotter is drown of opinist the moternal soft parts by the fixed position of the shoulders of the inlet. The correct manner of grasping the hood. The honds ove crossed so that the left hond grosps the head over the occipint. The right hond fixes the chim. The pull of the left hond is downward and to the mother's right.

In right occiput positions the procedure is simply reversed.

In case of serious shoulder arrest, where considerable pull is required, traction should be brought intermittently, in order not to interfere too much with the circulation in the vessels of the neek. While in the ordinary case of arrested shoulders a slight pull will be sufficient to effect descent, one need have no fear of exerting considerable traction in case of necessity provided that it be done intermittently and in the manner indicated.

This method has been employed for a period of fifteen years with uniformly good results. It will prove inadequate only in those rare cases where embryotomy offers the only solu-

tion.

Discussion (Closing)

The stress laid in my presentation upon the value of the maneuver in the prevention of brachial paralysis does not overlook the fact that the paralysis may occur in other than vertex presentation with arrested shoulders. Various degrees of injury to the nerves sup-

plying the arm have followed forceps deliveres and have been attributed to pressure of the blades on the neck. The injury has also resulted from difficult extraction of the aftercoming head in breech cases. Nevertheless, it is not easy to see how mere pressure of the blades can cause tearing of the deep nerves of the plexus; and as to breech deliveries, the mechanism of the production of the paralysis must be the same as in vertex presentation, a lateral pull of one shoulder away from the head.

Many descriptions of how the injury is produced have come from neurologists and orthopedists who often reach their conclusions by eliciting a history of forceps, but without being in a position to learn what happened after the delivery of the head. They therefore associate the accident with forceps.

Thomas and Seuer have analyzed 471 cases

FIGURE 4 Note that the traction applied results in descent of the posterior shoulder.

and have shown by experiments on cadavers that tearing of the lower cervical nerves can be produced by stretching one side of the neck.

The cause of arrested shoulders is sometimes said to be a contraction of the lower uterine segment around the child's neck. Such explanation has even been advanced for a retained placenta. The ease with which the shoulders are made to come down by the manipulation described is sufficient refutation of such explanation and need not lead to a discussion of the activity or passivity of the musculature of the lower segment. But the absence of such contraction may easily be determined by digital examination

The facilitation of shoulder descent by the method given is undoubtedly due to their rotation into the transverse pelvic diameter.

SOME NEUROLOGICAL ASPECTS OF SUPRARENAL INSUFFICIENCY

By LEON HASTINGS CORNWALL, M.D., NEW YORK, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at Buffelo, N. Y., May 25, 1932.

It is generally recognized that a number of diseases of extraneural origin may be initiated by symptoms of neural dysfunction. Neuritic symptoms in diabetes, cord symptoms in pernicious anaemia and mental symptoms in thyroid disorders are familiar examples. Clinical evidence of impaired cerebral function in intoxications due to alcohol and lead, the deliria associated with infections and the mental changes accompanying nutritional disturbances, such as pellagra and vitamine deficiencies, are not uncommon in the experience of every internist.

In suprarenal insufficiency one usually encounters the common manifestations of asthenia, hypotension, skin or mucous membrane pigmentation and gastro-intestinal derangements early in the course of the disease and neurologic symptoms, when present, are late incidents. On the other hand abdominal pains simulating gastric arises, lethargic states, reminiscent of epidemic encephalitis, or sudden coma suggesting cerebral neoplasm or vascular accident, may be the presenting symptoms

toms.

Current views of disease of the suprarenal body envisage two pathological entities, one being due to localization in the gland of inflammatory lesions, of which tuberculosis and syphilis are the most frequent, and the other representing a primarily degenerative process. Inflammatory processes usually involve both cortex and medulla whereas those of a primary degenerative nature are confined largely to the cortex of the gland. The classical syndrome of Addison's disease has been considered to be related to pathology of both cortex and medulla. The cardinal symptoms consist of secondary anaemia, bronzing of the skin. gastro-intestinal disturbances, asthenia, low blood pressure and progressive cachexia.

The suprarenal body represents a union of two components that are physiologically and histologically distinct. The medulla belongs to the chromaffin system, a part of the sympathetic, and the cortex is a part of the interrenal system. It is obvious that a variable symptomatology should be produced by disease of this organ depending upon the localization and extent of the pathology resident in it, as well as upon the inherent constitu-

tional endowment of the tissue itself.

It is not the purpose of this contribution to discus in detail the syndromes attributable to suprarenal disease because its intimate physiologic relationship to other endocrine organs would require an excursion into the broad field of endocrinology. It should be mentioned, however, that adrenalin is a product of the medullary substance and that its pharmacologic action is manifested by stimulation of the sympathetic system although some

degree of selectivity is apparent and certain structures, notably the sweat glands, which are innervated by the sympathetic, are not affected. The medullary tissue hormone produces vaso-constriction, especially of the splanchnic area, a rise in blood pressure, a lowering of tone of the intestinal musculature with inhibition of peristalsis. contraction of the uterine muscle, relaxation of the bronchial musculature, activation of the intestinal glands with the exception of the pancreas. mydriasis, enophthalmos and a mobilization of sugar as evidenced by hyperglycaemia and glyco-Hypofunction of the suprarenal medulla has been considered as productive of hypotension, low pulse pressure and hypothermia. The presence of Sergent's white line and asthenia are associated symptoms.

Hyperfunction of the suprarenal cortex is believed to be productive, directly or indirectly, of pseudohermaphroditism, pubertas praecox and adult hirsutism. To cortical hypofunction have usually been ascribed the asthenia and gastro-intestinal disturbances associated with Addison's disease. Our knowledge, based upon experimental data, is as yet too meager to warrant an attempt to make a clinical differentiation of symptoms due to lesions in one or the other component of this organ. It is fair to assume that the intimacy of their spatial relationship implies a certain inter-

dependence in their physiologic activity.

Since 1927 we have been aware of the fact that an adrenalin-free extract of the suprarenal cortex would prolong the life of completely suprarenalectomized animals for five to fifteen days beyond the survival period of controls and since 1930 we have known that concentrated extracts of this same tissue would prolong indefinitely the survival period of suprarenalectomized cats. Only recently has this product, known as cortin or interrenin, become available for general clinical use and the results so far attained justify the hope that it will be the means of saving and prolonging the lives of some individuals suffering from suprarenal cortical insufficiency. It would also seem certain that some of the symptoms formerly ascribed to hypofunction of the medulia of this gland are more properly attributable to deficiency of the cortical hormone.

My purpose in this contribution is to re-emphasize a few of the neurologic phases of suprarenal deficiency.

Case 1

As an instance of a problem in differential diagnosis that came under my observation two decades after diagnosis is made, is imperative if it is to accomplish the maximum degree of effectiveness.

ago might be mentioned the case of a street car conductor, thirty-two years of age, who for no obvious reason fell from his car to the pavement and was removed to a hospital in an unconscious condition. The possibilities of uraemie coma, diabetic coma, eerebral vascular accident, brain tumor or concussion, with or without fractured skull, required consideration. It was noted that there was a diffuse brownish-blue pigmentation of the forehead and hands but otherwise the physical examination disclosed no pathology of the integument, thoracic or abdominal viscera. The blood pressure was 100/65. X-rays of the skull disclosed no fracture or other intracranial pathology. Uraemia and diabetes were excluded by examinations of the urine and blood. The blood Wassermann was positive. No localizing symptoms of organic brain injury became manifest and the patient remained in stupor most of the time, emerging from it for short periods only. On these occasions, however, the mentality was confused and orientation for time, place and persons was lacking. The spinal fluid was normal in all respects including scrology and pressure. There were no changes in the fundi.

The sudden coma with normal urinary findings and blood chemistry, absence of clinical evidence indicative of any localization of cerebral pathology and positive blood serology, suggested syphilitie disease of the brain. Within twenty-four hours the blood pressure dropped to 80/50 and shortly before death, which occurred on the third day, the pressure had dropped to 65/35. This pointed to suprarenal disease which was confirmed at autopsy by the discovery of bilateral gummata

CASE 2

Spasms of abdominal pain suggestive of gastric crises may be the most prominent symptoms of suprarenal insufficiency. These are frequently associated with anorexia, eructations of gas, a sense of fullness after the ingestion of small amounts of food and nausea with or without vomiting.

Within the past few months I have seen a young girl of fourteen whose symptoms developed rather gradually in the late spring of 1931. Up to that time she had been over-nourished, the weight being 150 pounds. There was excessive growth of hair on the arms and legs with masculine character in the distribution of the abdominal hair and the whole habitus suggested hypopituitary function.

There was a gradual loss of weight and appetite, associated with paroxysms of abdominal pain which came on suddenly and were described as "knife-like," originating in the umbilical region and radiating to the flanks and back. These paroxysms occurred at intervals of one-half to one hour and lasted for three to five minutes. When first examined in November 1931 the weight was 90 pounds, representing a loss of 60

pounds in five months. There was evident anaemia of the skin and mucous membranes but neither bronzing of the skin nor abnormal pigmentation of the mucous surfaces except for a bluish color of the circumcorneal region. physical examination disclosed no pathologic findings in the mouth, throat, thoracic or abdominal viscera with the exception of sinus arrythymia and prolonged expiration over the left apex. neurologie examination disclosed a fine tremor of the tongue, convergence weakness of the right eye and hyporeflexia in the lower extremities. Motility and coordination were normal. There was a general weakness and fatigability of all of the body musculature but there were no localized atrophies, no pathological reflexes nor any disturbances of sensation. Sergent's line was demonstrable. The blood pressure averaged from 108/70 to 80/50. The urine was normal, blood Wassermann was negative, feecs were negative for parasites and ova and the chemical constituents of the blood showed no variation from the normal. Sputiim was negative for tuberele bacilli. Roentgenologic examinations of the skull, chest and gastro-intestinal tract revealed no pathology. The blood count disclosed a mild secondary anaemia and the examination of the urine for ereatine revealed an exerction of 362 mg. in twenty-four hours.

Administration of cortin was advised and it was given intravenously in amounts of 5-10 e.c. every second day for six weeks. This resulted in a diminution of the frequency of the attacks to about ten a day and the duration was reduced from three minutes to one minute or less but there was no gain in weight nor was the blood pressure altered. There were intermittent febrile episodes with an occasional rise to 103° F. Although the roentgenograms disclosed no pulmonary pathology and physical signs did not warrant such a diagnosis, the view was entertained that tuberculosis was existent, perhaps in the lymphatic system of the thorax or abdomen. Unfortunately this patient discontinued treatment and when last seen, one week ago, had lost ten pounds more in weight, the blood pressure was 80/50, and diarrhoea had become a prominent symptom. The diagnosis of suprarenal insufficiency would appear to be beyond contradiction.

So far as I am aware emphasis has not been placed upon an increase of creatine in the urine in this condition, although it is known to be an accompaniment of myasthenia gravis, the fasting state, fever, malnutrition and diseases associated with disintegration of muscular tissue. Doubtless the last factor was largely responsible in this case.

CASE 3

Another experience has emphasized the resemblance of suprarenal disease and cpidemic encephalitis. A married woman of twenty-one

years was seized suddenly on October 24, 1930, with profuse vaginal hemorrhage followed by syncope. The hemorrhage continued for twentyfour hours when a gynecologist was summoned. Naturally the suspicion of incomplete abortion was entertained and immediate hospitalization was Gynecological examination reaccomplished. vealed no pathology in the pelvic viscera. As the ordinary conservative measures were not successful in controlling the hemorrhage a transfusion of 1000 c.c. of blood was administered.

Although the hemorrhage ceased after the transfusion and there was improvement in the general condition, the patient remained somnolent. She emerged occasionally from this state but was confused, irrational and mildly delirious. continued in this condition for several days and I was asked to see her on October 29, 1930. During the examination she was restless and asked The responses to many irrelevant questions. questions and commands were slow. Orientation for time, place and persons was impaired but quite variable. For short periods she would be lucid and then suddenly would relapse into an apathetic and lethargic state. The temperature was 102.6° F, the pulse 120, and respirations 20. Blood pressure was 110/70. The skin was dry, smooth and sallow in color but no pigmentation was noted. The breath was foul; teeth were in good condition; tonsils were hypertrophied but not inflamed; pharynx was normal. Aside from a soft, blowing systolic murmur the thoracic and abdominal viscera disclosed no abnormalities. The neurologic status was normal. The laboratory findings were:

Urine—Amber, turbid, 1015, albumin trace, sugar 0, indican normal, occasional hyalin cast, moderate number of leucocytes; kidney function -normal to dye test; blood-haemoglobin 60, thruêr observation this preparation was not available. erythrocytes 4,250,000, leucocytes 9,200 with 43% neutrophiles, 47% lymphocytes, 8% monocytes and 2% eosinophiles; urea 73 mg., sugar 88 mg.; Wasermann and Kahn negative, culture negative, bleeding time three minutes; spinal fluid-clear, slightly increased pressure, cells 11, globulin 0, Wassermann negative, colloidal gold negative.

There were periods of lethargy with mild delirium alternating with short intervals of psychomotor hyperactivity, accompanied by hallucinatory episodes and hypomaniacal over-productivity. The latter were of short duration followed by a gradual transition into a state of apathy or som-There were short intervals when the nolence. consciousnes was relatively clear.

In view of the moderate febrile reaction, the tendency to somnolence and the mental confusion. encephalitis was considered as a possibility but the increased blood urea, in conjunction with a blood pressure of 106/60 and practically normal urinary findings, was extremely puzzling at the g-

The possibility of error was entertained but on repetition the blood chemistry disclosed urea 78.9, 65.4 and 77 mg., and sugar 113, 101 and 111 mg. on subsequent examinations.

The condition remained essentially unchanged for ten days, the temperature ranging from 99.4° to 108.8° F., pulse 90 to 118 and respirations 20 to 24. On November 10th she had a chill followed by a rise of temperature to 105° F., with a pulse rate of 150 and a drop of blood pressure to 65/30. A lumbar puncture at this time showed 12 cells with all other findings normal. On November 11th, 1930, following an intravenous injection of glucose, there was circulatory collapse and a drop of blood pressure to 30/0. There was little response to hypodermic administrations of caffein and adrenalin or to saline infusion and death occurred at noon of that day.

The autopsy revealed an absence of the right adrenal and extreme atrophy of the left. This was associated with a small heart, persistent thymus and tuberculosis of bronchial and mediastinal lymph nodes.

The slight hyperthermia, lethargy, somnolence, mental confusion and cell counts of 11 and 12 cells, respectively, in the absence of any pathologic findings in the thoracic or abdominal viscera or pigmentation or of significantly low blood p sure until the terminal stage of the illness rhis tated against the diagnosis of suprarenal insion ciency. The high blood unea on several oct sions without evidence of renal pathology shows have given a hint as this has been reported f quently since the renewed interest in this con tion that has been stimulated by the discovered animals of proceed that this patient able and we were not in possession of the valuabi information that has come from workers in thi field during the past, two years. It is now know, that some of these patients do not tolerate we intravenous administrations or transfusions, tha the reshold for shock is extremely low and the everyses rejical procedure, no matter how mino

must be to proached with caution.

In the first the sudden coma was probably an indication of platory collapse due to influences operative in the sympathetic nervous sys-The crises of visceral pain in the second case also probably represented a paroxysmal dysfunction of the sympathetic system. Whether the cerebral symptoms in the last case were the result of anoxaemia of the brain due to vasoconstriction of the cerebral arterioles or, on the contrary, to loss of vascular tone with vasodilatation, is a conjectural matter that I do not feel disposed to speculate about at this time.

It is worthy of note that, in addition to the classical symptoms that have already been mentioned, the tendency for a rise in the nitrogenous concentration of the blood, in the absence of manifest evidence of renal pathology, the occurrence of hypoglycaemia and an increase of the creatine excretion, are valuable points for differential diagnosis. In the instances that I have cited hypoglycaemia was not noted but excessive creatiniria was present in the second case and I believe this to be an important feature of the metabolism.

In conclusion I would emphasize that suprarenal insufficiency may manifest itself clinically by an abrupt onset of coma, that will require differentiation from uraemia, diabetes, concussion with or without skull fracture, ccrebral neoplasm and cerebral vascular accident: by gastric crises of an acute nature similar to those encountered in certain lesions of the spinal cord, and by the lathargic state and mental apathy that are such characteristic features of epidemie encephalitis.

Acknowledgment is made to Drs. Wilbur Ward and W. W. Herrick for permission to use some of their clinical data in the third case mentioned in this article and to Dr. Frederick Tilney for access to the clinical records of the N. Y. Neurological Institute covering the second and third cases.

day polistulosis vacciniformis acuta (juliusberg) followed by anuria AND TETANIC SPASTICITY

A Complicating Disease of Infantile Eczema

By HERMANN FEIT, M.D., NEW YORK, N. Y.

Crom the Department of Dermatology, Vanderbill Clinic, College of Physicians and Surgeons, Columbia University, New York, and read at the Annual Meeting of the Medical Society of the State of New York, at Huffalo, N. Y., May 24, 1932. sINFANTILE eczema, although a troublesome skin disease which demands all the wit Finkelstein.

of a dermatologist and the cooperation of the parents for its control, runs as a rule a penign course. When, however, an infection of the eczematized area takes place, the prognosis Decomes doubtful. In well-nourished children one finds not infrequently pyogenic infections around the hair follicles following miliaria or maceration of the skin by exudate, but furunculosis seldom appears. This mild folliculitis, sometimes referred to as pustulosis, can be controlled by the application of sulphur or by permanganate baths.

On the other hand, in children with chronic disturbance in nutrition a cellulitis may develop or the folliculitis may take on a more severe form. There is a sudden outbreak of papules which become pustules, which may be accompanied by high fever and swelling of the eczematized area. These severe types are known as impetigo simplex or pustulosis of

A rare variety of severe pustulosis is described by Juliusberg under the name pustu-A brief history of his losis vacciniformis. case which resembles closely the one here reported would present the picture of this rare disease. His patient had developed infantile eczema at the age of six months and later developed an eruption of flat papules on the face, scalp, and palms. The papules later developed into pea-sized, round, elevated vesicles with a depression in the center the size of a pin head or lentil. They resembled the lesions of vaccinia. One side of the face was evenly covered with a humid, soft, yellowish, waxlike mass. There were no lesions on the mu-cous membrane. The child developed a high fever and after a course of several weeks, died, apparently as the result of this skin infection. At autopsy no visceral lesions were found.

The patient had not been vaccinated. The vesicles did not show the red halo usually present in chicken pox and vaccinia and were distributed only in regions which could be reached by his fingers. The early lesions were The older lesions showed not cultured. staphylococci in great numbers. The mother had a stye from which child might have be-Juliusberg concludes: "We come infected. are dealing with a skin disease which at first could be mistaken for chicken pox, variola, vaccinia, but which can clinically and microscopically be distinguished from those conditions. The efflorescenses all show the same stage of evolution and represent at the height of their development pustules which can heal without leaving a scar. Staphylococcus aureus seems to be the infecting agent."

Baar and Freud recently reported several cases of pustulosis vacciniformis. One, a boy, eight months old, affected with eczema of the face and bronchial asthma, was suddenly taken sick with a high fever and an outbreak of small vesicles, which resembled those of vaccinia, on the face. The patient developed tonic and clonic convulsions and died after three days. Culture from a vesicle showed

FIGURE 1

FIGURE 2
On February 15, 1932.

staphylococci. Inoculation of a rabbit's cornea produced a severe keratitis. Guarneris bodies were not found. There was no history of exposure to vaccinia. The spinal fluid was negative. Autopsy showed parenchymatous swelling of the viscera and acute edema of the brain. These authors observed two other cases which terminated fatally. They conclude that pustulosis vacciniformis is either a peculiar type of reaction in a patient with eczema, or an infectious disease caused by an unknown filterable virus.

Report of a Case

The case here reported was an infant of four months. Past History: There was no history of contagious disease or of recent exposure. The child had occasional colds. She had not been vaccinated and no other immunization methods had been employed. At the age of three days she was weaned on account of inversion of the mother's nipples. At the age of two weeks she developed an eczema of the face and to a lesser degree of the body for which she was under my care. Under alteration in feeding and the use of local applications the eczema became practically clear. The infant had a good appetite, no gastric disturbances, and development appeared normal. For three weeks before the outbreak of her eruption she had been given the following formula:

Seven feedings of six ounces. Viosterol ten drops a day, orange juice occasionally. Before the outbreak of the present eruption the child had been given for the first time, The next day bath with castile soap. the face became inflamed and two days later a pustular eruption appeared on face which quickly spread to the oral mucosa making feeding painful. There was at first no apparent pain or fever and no convulsions. When first seen on January 1 there was a recurrence of the eczema on the face and scalp which were covered with thick, greasy scales and crusts. Superimposed on these lesions were multiple pea-sized pustules, the tops of which were flattened and umbilicated in the center. Pustules were filled with grayish liquid mixed with bloody serum. A few similar pustules were present on the chest. In the mouth were small white patches resembling lesions of thrush and the right side of the face was covered with a milky exudate which seemed to be connected with the mouth lesions. In spite of the grave dermatological picture, the general condition of the child did not seem much impaired although there was slight fever. On account of the resemblance of these lesions to those described by Juliusberg the prognosis seemed grave and the child was referred to the Babies Hospital where it was admitted the following day on the service of Dr. Herbert B. Wilcox. By this time the pustular lesions had collapsed and had become crusted. The following note was made:

Physical Examination: A poorly-nourished infant lying quietly in bed. The skin of the face is swollen and inflamed with numerous crusted, cracked, bleeding lesions involving the entire left side, most of the right, the ears, and to a

less extent the scalp, where, however, there was only crusting. The left eye was closed due to involvement of the lids, the right less involved. There was a purulent discharge from both eyes. The lips were swollen, although the immediate circumoral skin was little involved. There were numerous circular white raised patches varying in size from one to three millimeters on the outer tongue, gums, and inner side of the lower lip. These bled freely when touched with a tongue depressor. A few crusted lesions were present on the anterior neck and left shoulder, impetiginous in character. There was a mild intertrigo on the buttock and right popliteal space. Except for moderate rigidity of the neck, hyperactive reflexes, no other abnormal findings were `~erved.

Laboratory Findings: The blood count on admission showed RBC 3,650,000, WBC 35,750, Hemoglobin 64%, PMN 61%, lymphocytes 30%, monocytes 2%, eosinophiles 15%. The urine showed a trace of albumin with a few casts and pus cells. Smears of the mouth lesions showed pus cells and gram positive No Vincents organisms were found and cultures for thrush organisms were negative. Kahn tests was negative. Blood culture was negative.

Course and Treatment: The lesions were treated by the application of boric acid ointment and exposure to air and the child seemed to improve until January 8 when a fresh outbreak of impetiginous lesions appeared on the chest. The temperature during this time varied from normal to 105. The ointment was then discontinued and 3% mercurochrome anplied and generalized treatments with ultraviolet light were begun. In three days the spread of the eruption ceased but two days later the child, who had not voided for thirty hours, developed a spastic retraction of neck and spasticity of the legs and appeared dehydrated. The prognosis at this time seemed grave. Infusions were given of 120 cc of 5% glucose intravenously, 150 cc of normal saline hypodermically, and 0.8 cc of chloral hydrate per rectum. On January 14, after repeated clyses, the temperature became normal and the general condition much improved. January 16 the ultra-violet light treatment was discontinued. Compresses of potassium permanganate solution 1-6000 were applied every three hours and the lesions allowed to dry in the intervals. Luminol 0.015 gms, was given twice daily when necessary to control restlessness. The eyes were irrigated twice daily with boric acid. Under this regime the skin continued to improve and the temperature remained normal. On one occasion cold eream was applied to the face and there promptly appeared tiny vesicles suggestive of the early lesions. These disappeared when cream was discontinued. By January 26 the erusts had disappeared, the child gained weight, and he was discharged practically cured.

Comment: This case is believed to represent an example of the pustulosis vacciniformis acuta of Juliusberg terminating in recovery. The characteristics of the disease are the outbreak of vesicle pustules simulating those of vaccinia limited chiefly to the exposed areas in a child suffering from infantile eczema. A high fever and symptoms of irritation of the eentral nervous system seem characteristic of this disease. The lesions are distinguished from impetigo by their vacciniform character and from chicken pox, small pox, and vaccinia by their distribution and evolution, by the absence of history of infection, and by the course of the disease. The cause of the disease is unknown. It is possible that it is due to some filterable virus, otherwise one must assume an increased virulence of the staphylococcus or a decreased resistance on the part of the patient.

Your talkes to the state r of the Babies to Dr. Jas. F. Kingsbury and

PHYSICAL THERAPY IN GYNECOLOGICAL OFFICE PRACTICE

By VIRGINIA TANNENBAUM, M.D., BUFFALO, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

I-MEDICAL DIATHERMY

A-Medical diathermy in specific infections.

1-Medical diathermy or the therapeutic application of the high frequency current, within normal physiological limits, has a place in the treatment of acute specific salpingitis. During this stage of the infection, local treatment should be deferred. The use of prolonged hot douches and such analgesics as may be necessary should not be omitted.

- The technique for thru and thru or "trans-pelvic" diathermy is definitely established and in popular use. The posseven-by-ten electrode. about inches in size, is placed over the sacrum while the anterior electrode, five-by-seven inches, is placed over the symphasis pubis. The milliamperage is about 1,000 to 1,200 and is given for forty-five to fifty minutes. At the institution of treatment diathermy should be given daily, gradually, lengthening the time interval, between treatments, as the patient's condition improves.
- 2—Sub-acute specific tubal infection gives the most gratifying response with medical diathermy. It lessens the discomfort, decreases the vaginal discharge and hastens the absorption of the inflammatory exudate, and many times allows the patient to remain ambulatory.
- 3—Chronic specific salpingitis can be divided into two groups, namely:
 - (a) The cases where the tubes are palpable and moderately tender, with or without a positive smear, usually without.
 - (b) The cases, that on palpation, show exquisite tenderness and often a mass or masses in the fornices.

The first group or those with the less severe infection are entitled to the benefit of adequate treatment with diathermy before salpingectomy is considered. The majority will improve and stay improved if sufficient treatment is given.

In the second group, if the patient is willing to temporize, diathermy can be tried, particularly if the patient is anxious to retain the childbearing function. However, in my experience these large "pus tubes," sometimes the size of a small orange, and often complicated by ovarian abscesses, are not amenable to treatment with diathermy. Surgery, in these cases, may allow the total removal of the grossly infected material and, yet, possibly, the preservation of sufficient ovarian tissue to avert a surgical menopause.

- 4—Post-operative adhesions in pelvis, specific or non-specific, are one of the salient indications for "trans-pelvic" diathermy.
- 5—Acute specific cervicitis should not be treated locally.
- 6—Endocervicitis, following an acute specific infection treated with intra-cervical medical diathermy has shown no appreciable improvement in my experience.
- B—Medical diathermy in non-specific infection.

- 1—Post abortive broad ligament infection should not be treated by diathermy.
- 2-I have had four cases that I feel have had pelvic tuberculosis. In two of these, the diagnosis of pelvic tuberculosis was made at the time of operation. The other two cases, on pelvic examination, showed tender, fixed adnexa, had a purulent discharge, negative smears, and also had definite physical findings of pulmonary tuberculosis. All four were ambulatory. These women, in addition to the usual rest, high vitamine diet, etc., received "trans-pelvic" diathermy and also general ultra violet ray, approximately twice a week for six months. The results were surprisingly gratifying. There was a softening of the pelvic adnexa, a decrease in tenderness, a marked lessening of the discharge as well as a great improvement in the general condition.

II—SURGICAL DIATHERMY

The term surgical diathermy is used to designate the application, for therapeutic purposes, of the high frequency current at a temperature exceeding normal physiological limits, for the purpose of effecting a destruction or removal of tissue. The extent of this destruction or removal varies from a simple drying of tissue to a massive removal of tissue. The three usual forms of surgical diathermy are: electro-desiccation, electro-coagulation, and the high frequency cutting current.

Electro-desiccation causes a drying or dehydration of tissue. This is accomplished by the use of the spark, that is derived from the Oudin resonator, attached to the d'Arsonval selenoid. It is a mono-polar current. The needle point electrode is connected to the Oudin terminal and is held in contact or at a sparking distance from the area to be treated. The intensity of the current is regulated proportionally to the amount of destruction desired. Electro-desiccation is indicated in "the destruction of superficial growths and lesions of the skin and mucous membrane." 1

Electro-coagulation is a bipolar form of surgical diathermy. The small, active electrode is connected to either of the electro-coagulating terminals, with the large dispersing electrode connected to the other terminal. The active electrode is placed in contact with the tissue to be destroyed, resulting in a coagulation of the tissue. This is a very satisfactory modality and can be used in the destruc-

tion of much accessible pathological tissue. Chronically infected cervical glands, polyps, caruncles, condylomata, can usually be adequately treated with the electro-coagulating electrode. For gynecological work, the bi-polar electro-coagulating electrode perfected by Dr. Thomas H. Cherry offers great possibilities in the treatment of endocervicitis and of cervical erosions.

The high frequency cutting current has for the active operating electrode a suitable needle, wire, or blade. The procedure entails a "coring" of the cervical canal.

A-Indications for surgical diathermy.

1-Chronic cervicitis, specific or otherwise in origin, may be associated with a co-existing endocervicitis, and, in turn, this endocervicitis may be the cause of the cervicitis. Again, we may have a chronic cervicitis without an endocervicitis. Chronic eervicitis usually presents a varying degree of erosion of the cervical mucous membrane. Nabothian cysts can be satisfactorily punctured and the eroded surface stimulated by the electro-desiccating needle. A more severe cervicitis may require electro-coagulation. If the cervicitis is associated or complieated by an endocervicitis, the cervical canal should, in addition to the above procedure, be treated by electro-coagulation.

2-Chronic endocervicitis.

I believe, at this moment, at least, that the use of the Cherry bipolar electrode gives the most satisfactory results in electro-coagulation of the cervical canal. The electrode is inserted into the cervical canal for approximately one-inch. When the electrode is properly placed, with the current set to approximately three-hundred to four-hundred milliamperes, the electrode should be swiftly and gently rotated in the cervical canal for about fifteen seconds. It is essential that the electrode be in position in the cervical canal before the turning on or off of the current. Better results seem to be obtained with an initial mild application, repeated several times, if necessary, at intervals, of five to six weeks. There is a uniform destruction of tissue around the site of the electrode as can be seen at the time of treatment.

If, the cylindrical epithelial lining of the cervical canal, with its contributary glands, when destroyed, is replaced by squamous epithelium from the vaginal eervix, the possibility of cervical stenosis as well as the possibility of any further eervical glandular activity is removed. In many instances, the electro-coagulation of the cervical canal suffices to cause a healing of the cervical erosions. However, if the endocervicitis is associated with a particularly extensive cervicitis and especially with the presence of large Nabothian cysts, the eysts should be punctured with the electro-desiccation needle as before advised. Then, after, the above described electro-coagulation of the cervical canal, the vaginal speculum can be collapsed and with the Cherry bipolar electrode, partially withdrawn, the electrode can again be rotated in a larger circle in order to contact the eroded surfaces of the cervix. The combined electro-coagulation of the cervical canal and cervical erosion with adequate clectro-desiccation of the Nabothian cysts offers today, I believe, the simplest and most efficient form of treatment of combined cervicitis and endocervicitis.

- 3—Specific infection of Skene's glands, in my experience, has been wholly resistant to intraurethral medical diathermy. However, these glands can usually be destroyed with the electro-desiccation needle. Care must be taken to treat only one side at a time because of the resultant oedema of the urethal mucous membrane.
- 4—Urcthral caruncles can be removed by electro-desiccation or electro-coagulation; in fact, the time-honored cautery is frequently useful in the removal of these growths.
- 5—Accessible polypoid degenerations can be removed by practically any surgical diathermy current. The removed tissue should be sent for microscopic examination. However, I believe, that, where sufficient degeneration is present to have resulted in polypoid formation, that a diagnostic curettage is the method of choice. This allows for the complete removal of the pathological tissue. Also, a diagnostic curettage allows for the use of small quantities of radium which may be of great benefit in these degenerations.
- 6—Warts or condylomata are best removed with the electro-desiccating needle or by electro-coagulation. The base of the growths should first be adequately infiltrated with a one per cent novocaine solution. Care should be taken that the destruction of the growths be of sufficient depth to prevent any recurrence.

III-MEDICAL GALVANISM

Cumberbatch states that "The most valuable therapeutic property of the galvanic current is its power to aid the absorption of inflammatory products."²

- A—Galvanism from the positive pole produces an acid condition with a shrinkage and contraction of the tissues and, has been used for years in the treatment of chronic, swollen, eroded cervicitis.
- B—Galvanism from the negative pole has many advocates. Dr. Kovacs1 states "Negative galvanism is an efficient means of gradually dilating a congenitally stenosed cervix. A metal cervical electrode is connected to the negative pole and a dispersing pad, placed about the symphysis, is connected to the positive pole. One should first apply an active electrode of smallest diameter, insert it under antiseptic precautions, turn on 1 to 3 milliamperes of current at first and increase its amount, always within comfortable toleration, to about 10 milliamperes. After a few minutes white bubbles appear all around the electrode in the cervix and it can be easily. moved about. It should now be replaced by the electrode next in size, which easily slips in the softened cervical canal; a still larger electrode can be inserted perhaps once more, during a total treatment-time of fifteen to twenty-five minutes. In the infantile uterus after the dilation of the cervix, the last electrode should be left "in situ" and the surging faradic or sinusoidal current turned on, causing gentle contractions for from fifteen minutes to one-half hour. This treatment should be repeated twice a week for a period of several months, avoiding the proximity of menstrual periods."1

Still quoting Kovacs, "Dannreuther of the Post-Graduate Hospital, in New York, reports that the cervix can be gradually and painlessly dilated by this means, and there is nothing that can be accomplished by forcible dilation and the use of stems under anesthesia that cannot be done as well and with more permanent results in this way. He has used this method often in conjunction with organotherapy, for twenty years, in cases of dysmenorrhea and amenorrhea due to hypoplasia, with the utmost satisfaction" (Kovacs—1932—P. 448)

Possibly my cases have been rather unusual, or possibly the technique defective, but the results that I have obtained from the use of galvanism in gynecology have not been very encouraging.

IV—ACTINOTHERAPY

Sunlight needs neither plea nor proof of value. Ultra-violet rays produced by the quartz mercury burner, are of value because of their tonic effect on the human organism. As yet, there are many conflicting opinions as to their biologic and physiologic mode of action. However, I have often noted that anemic, emaciated girls, generally below par, having ultraviolet ray in conjunction with iron, a high vitamine diet, etc., and also frequently complaining of dysmenorrhea or a relative amenorrhea, have volunteered that they have had greater comfort at menstrual period, since having taken the ultraviolet lamp treatments.

V-HYDROTHERAPY

Water as a remedial agent, has a far greater field of application in sanitarium than in office practice. Nevertheless, the value of hot douches, serving as a cleansing agent, and, for local heat effect, on the vaginal mucous membrane, should not be forgotten in our enthusiasm over electro-therapy.

CONCLUSION

1—Medical diathermy is of value in the treatment specific acute, specific, sub-acute, and some forms of specific, chronic salpingitis. Medical diathermy may be of value in the treatment of tuberculosis of the pelvic adnexa.

2—Surgical diathermy offers a decided advance in the treatment of diseases, specific or otherwise, of the cervix and cervi-

cal canal.

3—Sunlight and ultra-violet rays, because of their effect on the human organism, are of benefit in the treatment of some types of dysmenorrhea.

THE VALUE OF ANTITOXIN IN THE TREATMENT OF SCARLET FEVER

By LAWRENCE A. KOHN, M.D., and A. IZARD JOSEY, M.D., ROCHESTER, N.Y.

From the Department of Medicine, University of Rochester, School of Medicine and Dentistry, Rochester, New York,

TT IS now (January, 1933) over eight years since Blakei reported the first results of treatment of scarlet fever with antistreptococcus serum prepared according to Dochez.2 In this period, although thousands of patients have received specific therapy, the results are not certain. From various quarters of the globe, enthusiastic, doubtful or unfavorable reports are on record. a, a, a, a, 7, 8, 9 Many of them deal with series of patients treated with serum without control groups not so treated; others deal with mortality alone. Since it is generally conceded that the mortality of scarlet fever has decreased, and is still decreasing, this criterion must be discarded in forming judgment. Moreover, the severity of the disease varies widely from place to place, from year to year and in differing age groups. Finally, it is now generally appreciated that the toxic features of the disease and those due to local or metastatic colonization of streptococci must be separately analyzed. Fever, rash, prostration are typically toxic symptoms; the complications must in general be regarded as the result of streptococcal infection and its sequelac.

We are reporting the effect on course and complications, of scrum administration in some of the 202 cases of scarlet fever treated in the Strong Memorial and Rochester Municipal hospitals during the six-year period from 1925 to 1931. These patients were all over 14 years of age, the majority falling between 15 and 30 years; no young children are included. Of the total, 89 were admitted from January, 1926, to June, 1930, chiefly in the fall, winter and spring months, and these were considered sporadic in type. In the fall of 1930 and the winter and spring of 1931, we experienced an increase in frequency of the disease amounting almost to an epidemic. The 113 patients of this period have been separately analyzed.

Of the total group, 127 were given serum, usually on or before the fourth day of illness, and 75 had no serum. The antitoxin was that prepared by the New York State Department of Health Laboratories according to the method of Dochez and the usual dose was 10,000 units.* Rarely, because of relapse, the dose was repeated. A few patients were given antitoxin by vein; the usual method of administration was intraunuscular. The dose was generally given within a few hours of admission to the hospital. The usual precautions in regard to serum sensitiveness and anaphylactic accidents were carefully followed.

On the basis of fever and general clinical appearance, we have arbitrarily placed these patients in mild, moderately severe and severe groups.

Leucocytosis does not parallel severity, as has also been noted by Wylie 10 nor does the percentage of streptococci to total flora in throat cultures as determined by the poured blood plate method. Patients who had fever of 38 centigrade or less on admission to hospital, and presented little or no prostration were considered mild. Cases with feyer up to 39.5 centigrade and moderate prostration were considered moderately severe, and those who had fever above 39.5 or who had very marked prostration were classed as severe. Complications were also arbitrarily divided into 'mild" or "severe." "Mild" includes otitis, sinusitis, cervical adenitis or transient arthritis. "Severe" consists of either multiple mild complications or pneumonia, severe and persistent arthritis, rheumatic fever, any evidence of renal involvement or any complication necessitating sur-gical intervention. While complications may have developed after our period of observation was over, their distribution should have been uniform between treated and untreated cases, and no follow-up study was attempted.

Treatment was identical in all patients save for the use of serum. Unless complications developed, patients were kept in bed until the 14th to the 21st day of disease. Fluids were forced during the febrile period and given parenterally if refused per os. Analgesics and ice bags were used to combat the pain of angina or cervical adenitis. Alkaline saline or aspirin gargle was used, and the diet, not restricted as to protein, was adapted to the general condition of the patient.

As a criterion of the effect of serum on toxic phenomena, we have analyzed our material for the duration of fever in Tables 1 and 2. The duration of rash followed closely that of fever, and malaise and prostration were similarly favorably affected by serum. These results seem partly a function of time of treatment: the duration of fever was decreased most when serum was given on or before the fourth day of illness. It also appears that hospitalization alone shortens the toxic period; those cases admitted on or before the fourth day and to whom serum was not given show a definite reduction in duration of fever as compared to those admitted later in their illness. In Table 2, it should be kept in mind that 40 per cent of untreated cases were classed as mild, as compared with 14 per cent of those who received serum.

In Table 3, the effect of serum treatment on complications is considered. While the percentage of complications in mild and severe cases is lower in the treated group, the number of observations is small and the differences doubtfully significant. In the moderately severe group, the

The unit of scarlet fever antitoxin is now standardized as the amount which will neutralize 50 skin test doses of toxin.

typical adult scarlet, the incidence is increased in the treated cases. An analysis of the results according to day of treatment gave no change in the figures: in patients treated on or before the fourth

ences can be found in the sporadic and epidemic cases.

Discussion.—It appears that the toxic features of the disease are lessened by serum treatment, especially if it be administered fairly early. In a similar group of patients treated in their homes, it might be expected that earlier diagnosis and treatment might increase this difference. Complications, taken as an index of the septic factors in the disease, were not influenced by specific therapy though emphasis might be placed on the lessening of serious complications: one patient in thirteen among the treated, as against one in nine in the untreated group suffered in this way. Mild complications are uncomfortable and not dangerous.

If we weigh the detoxification which can be almost uniformly expected from serum against untoward effects, we must consider four possibilities. First, anaphylactic shock is probably inexcusable, but we had two fairly severe instances, with vaso-motor collapse to such an extent as to arouse concern ad vitam. Second, over-emphasis on serum treatment is facile; scrupulous attention to septic foci is most important, and may be neglected unless it is clear that antitoxin does not relieve one of the likelihood of complications. Third, serum disease occurred in about 55 per cent of our patients, and while not dangerously ill, many of them suffered more than from their original scarlet fever. Finally, in the younger members of our group, or in younger children, sensitization to horse serum must be taken into account. The highly allergic individual will acquire sensitization

TABLE 4

		Serum Treated	_	N	Ion-Serum Treat	ed_
Cases prior to July, 1930	Number of Patients	Average days of Fever	Percentage of Patients with Com- plications	Number of Patients	Average days of Fever	Percentage of Patients with Com- plications
Mild	10	5.3	10%	11	7.9	15%
Moderately Severe	37	· 7.5	35%	19	10	15%
Severe	10	8,8	60%	0 .	-	
Mild	8	5.5	37.5%	16	6	35%
Moderately Severe	54	6.4	44%	20	9.9	35%
Severe	8	. 10.5	75%	6	11.6	83%

day of illness there were 38 per cent of complications. However, only 20 per cent of the complications in treated patients were "severe" as against 38 per cent in the controls. There were three deaths, two of them serum-treated, with broncho-pneumonia and empyema, and nephritis as cause, and one who received no serum, a mildappearing case, pregnant, who was delivered on the third day of illness and subsequently developed broncho-pneumonia and empyema.

In Table 4, it is seen that no essential differ-

in any case, but many border-line individuals will be the worse for having had serum.

Conclusions.—An analysis of 202 cases of scarlet fever in adults and older children, of whom 127 received antitoxin, shows a definitely favorable effect on the toxic symptoms of the disease. The high incidence of disability due to serum disease must be weighed against this effect. The incidence of complications is not affected by serum administration, although their severity may be lessened.

TRIPLE ANNUAL MEETING

The great event of the Medical Society of the State of New York is its annual meeting, which took place this year on April third to the fifth While this event occupied only three days, preparations for it required three months and descriptions of the actual events will continue to appear during the rest of the vear There are, in fact, three meetings: that which is planned, that which actually took place, and that which will remain in memory and record. These three meetings were identical to an extent that was probably never before attained

A test of the value of an annual meeting is its adaptability to description after the event. The Journal of April fifteenth contained a balanced outline of all the various events, and the inaugural and exaugural Presidential addresses. That of May first recorded the minutes of the House of Delegates and the analytical addresses of Dean Schwitalla and Doctor Haggard. This issue begins with the address of Dr. E., H. Carey, which sets forth the essential activities of the American Medical Association. The Journal throughout the year will print the scientific papers

MEDICAL PROPHECIES

The address of Dr. Howard W. Haggard on "The Decline of Medicine as an Art," and that of Dean A. M. Schwitalla on "The Master in the House of Medicine," both of which were published in the May first issue of this Journal, elicited hearty commendation when they were delivered at the Anniversary Meeting of the Medical Society of the State of New York on April fourth; and many suggestions were made to the editors to be sure to publish them. These addresses have the rare quality of "Growing upon the reader," and of revealing new points of view with each reading.

This editorial is intended to be an appeal to each member of the State Society to preserve his Journal of May first for reading at his leisure when he can grasp and retain the facts and arguments as the authors have presented them.

Every physician is a philosopher at heart, and frequently voices his complaint that the people do not appreciate the scientific services which he renders. He is also painfully aware that every writer, and orator, and street corner philosopher assumes the prerogative of telling him about the limitations of his science, and of proposing alluring methods of bringing a perfect therapeutic system to every person. But very few physicians can explain why these facts are true.

Doctors Haggard and Schwitalla draw upon history and experience to present the pathology of the attitude of the people toward scientific medical service in new lights which suggest both the diagnosis and the treatment of the condition.

Dr. Haggard describes the standing of the physician in three periods of history,—in ancient times, as a priest; in the Middle Ages, as a tradesman; and in these later days, as a scientist. If the modern physician is to deliver maximum service to the people, he must still be a priest who

understands things hidden from common mortals; a tradesman who impresses the people with the social and economic benefits of his service; and the scientist who commands the resources of nature and they obey him. But added to all these the physician must be the artist,—the skilled hand-worker,—whose products appeal to the emotions and cause men to rise up and proclaim the greatness and the goodness of the doctor.

Dean Schwitalla, who was a member of the National Committee on the Costs of Medical Care, but who did not subscribe to the published reports, discussed the question, "Who is Master in the House of Medicine." He named three contenders for the mastery:

- 1. Efficient mass production
- 2. Organization
- 3. Professional evolution

Dean Schwitalla's clear thinking shows itself in his discussion of professional evolution, in which he sees a danger of self-destruction, when he says:

"The foremost requirement for adaptation is the organism's or profession's self-preservation. If the organism does not adapt itself to changing environment, it will destroy itself; if it overadapts itself, it will also destroy itself. The future of medicine demands that it be allowed to develop as medicine, and not merely as an adjunct to social science."

The fame of the Biblical prophets did not lie so much in their foresight of future occurrences, as in their addresses which interpreted contemporary events in the light of past experience. Doctors Haggard and Schwitalla are medical prophets whose words will be an inspiration to every practitioner of medicine.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Sputum Cups: A quarter century ago the window tent and the sputum cup proclaimed the presence of the tuberculous patient. This Journal of May, 1908, described a sputum cup substitute which would be inconspicuous.

"There are upon the market, handled by the drug and rubber goods trades, pouches of various sizes, made of silk or gingham, lined with adherent rubber tissue, called sponge bags, around the mouth of each of which is a purse string running under a band, attached upon the cloth side about one inch from the top. They may be had in different colors.

"One of these, about eight inches wide by nine long, into which has been placed a flat, two pound size paper bag, with its purse string slightly drawn, looks very much like a sewing bag, or even one such as is often carried upon the street with handkerchief, purse, etc.

"This outfit is to be used to receive the crumpled slips of toilet paper into which the patient has expectorated, and that should be provided as thick and as absorbent as the market affords. Or the material used in paper napkins, or even filter paper, or pieces of muslin, may be used if cost is not a consideration."

MEDICAL PROGRESS

The Treatment of Frostbites and Injuries from Cold-In the treatment of all acute injuries from freezing, says Max Grasmann, writing in the Munchener medianische Wochenschrift of January 6 1933, it is of first importance to avoid any sudden transition from cold to warmth It has been established experimentally as well as clinically that only upon gradual and slow thawing out can the cells again fully absorb the water that has been extravasated from them. If an individual is found frozen stiff, he should, provided he shows the least signs of breathing, be carried into a cold room, his clothing removed and his entire body rubbed with snow or cold wet towels, a cardiac stimulant should be administered intra renously and if necessary, artifical respiration performed. If circulation and respiration are reestablished, the prtient should be placed in a both at room temperature, if such is available, and mas-During the lapse of several hours the water should be slowly warmed to 30° C and the patient given hot drinks if he can swallow. In the absence of a bath the room is slowly warmed, and the patient's entire hody rubbed with wet tonels, after which he is placed in a warm bed Local frostbites of first degree in the stage of angiospasni must be rubbed with snow or cold water until the skin becomes red Light massage should be given twice a day, and ichthyol glycerme bandages applied at night Long exposure of any part of the body to cold injures the vessels and may cause histers filled with blood or serum. this is a second degree frostbite The affected part is treated as above, then after good circulation is restored, the skin is carefully disinfected, the blisters opened, and a powder bundage applied to the part, which should be elevated If suppuration should occur, suitable antiseptic treatment is In a third degree freezing, tissue is destroyed If the affected part remains blue and anesthetic without restoration of circulation after several hours have passed, incisions to reheve tension are in order These may be crescent shaped around a finger nail or in the case of a hand or foot 2.4 incisions may be made on the flexor and extensor surfaces or on each phalanx, as the case may require These may result in considerable outflow of serous fluid, followed first by dark and later by bright red blood Even if these measures fail to stimulate a part, it is still uncertain whether the tissue may not be merely ischemic. It is astonishing to see how much apparently dead tissue can be saved. For this reason primary amputation is a mistake Mutilating operations are permissible only (1) when demarcation of necrotic from sound tissue is complete, (2) in moist gangrene,

(3) in the presence of tetanus. Infection must be sedulously guarded against; absesses must be opened, phlegmons lanced, and appropriate antisentic dressings applied.

Multiple Glandular Sclerosis - Karl Heimin, writing in Endocrinology, January-February, 1933, vii, 1, reports an unusual case in which the patient suffered from both Addison's disease and Graves' disease The symptoms were extreme weakness, emacration, vomiting, thyroid enlargement with visible pulsation and prominence and glittering of the eyes Intractable insomnia, deliruim, and incontinence were also prominent symptoms As the patient was a woman 53 years of age, the ovaries, as endocrine organs, could not give rise to serious disorder The symptoms of Basedow's disease were comparatively mild, the diagnosis was concerned chiefly with the question as to whether the condition was Addison's disease or Simmond's disease The surest sign of Addison's disease pigmentation, was absent. To clear up this question the patient was given prolan, as experience had shown that this hormone had effected a rapid improve ment in cases of Simmond's disease. In the present case no improvement occurred. As the possibility of Addison's disease became increasingly apparent, the hormone of the adrenal cortex (un der the trade name "cortigen") was administered The first striking result was that the patient slept almost continuously for three days, and upon awakening was brighter. From that time her eondition improved, the delirium, comiting and in continence disappeared, and the anemia improved In six weeks there was a gain in weight of nine pounds In very severe cases two or three ampules of cortigen are sufficient, when improvement sets in this quantity can be reduced to two ampules and afterward to one ampule a day Herman is of the opinion that the hormone of the suprarenal cortex is an excellently effective remedy for Addison's disease, and also an extremely important aid in diagnosis So long as Addison's disease is atypical and without dependable symptoms, it is the duty of the physician, in cases of obscure cachexia, to employ the cortex hormone until it is quite clear whether the organism requires it or not

Infectious Pharyngeal Catarrh and Irritative Coughs—It is pointed out by R von den Velden that the infectious diseases of the upper air passages that have been prevalent this winter have presented 2 different clinical pictures In the first, which is characterized by fever, often up

to 39° C., with marked prostration, headache, loss of appetite, etc., there is sometimes no other local finding than a severe pharyngitis, generally purulent, more rarely associated with a stomatitis, but without angina. The sinuses should of course be watched, and the blood picture controlled with reference to a possible agranulocytosis. cases the patient should promptly be given large quantities of tepid alkaline water to drink, and the throat and nose rinsed with camomile tea to loosen up the mucus. It is also useful to lay strips of trypaflavine gauze in the cheek pouches for 15 minutes at a time, several times a day, where the buccal mucosa is involved. If swallowing is painful, the use of menthol preparations, dysphagin tablets and gargling with novocaine solutions gives relief. Under no conditions should remedies having a caustic or astringent action be employed. Warm moist compresses about the neck and over the face, leaving openings for mouth and nose, are These somtimes give even more relief than light baths or vapor baths for the head, the use of which has been too much neglected. The other respiratory affection of which numerous cases have lately been observed, is a "spastic" bronchial catarrh, which may be the sequel of a feverish bronchitis, or may appear unheralded by any preliminary stage. The fact that many persons cannot or will not rest in bed when they have a cold accounts for the development of many dry irritative coughs. Starting in the pharynx, then rapidly descending to the larynx and trachea, the cough takes on the character in predisposed persons of whooping cough and may exert a detrimental influence upon the cardiovascular system, as well as in the respiratory and cerebral regions. In such cases the avoidance of fresh irritation to the air passages is often more important than the use of cough remedies. Physical exercises performed in a closed schoolroom without proper means of warm air ventilation are to be deprecated, since the stirring up of dust particles may produce endemic catarrh among school children. Hot drinks, especially of viscous substances, such as sugar water, milk with sugar, honey with milk or hot cream, are among the best means of relieving coughing attacks. In making use of the host of excellent cough remedies available, one should not forget that suitable rest and maintenance of an even temperature in a room hygienically warmed and ventilated are often the best means of combating a persistent catarrh.—Deutsche medizinische Wochenschrift, February 3, 1933.

Inflammation.—In discussing the difficulty of defining inflammation, George Lenthal Cheatle says that many text-books accept Burdon Sanderson's definition that "inflammation is the succession of changes occurring in a part, as the result of injury, provided that that injury be not so excessive as to destroy the vitality of the part."

Lister, in describing the inflammatory process, shows that an injured blood vessel is dilated to the state of temporary paralysis, stasis occurs, and red and white blood corpuscles tend to adhere to each other and to the blood vessel walls. With this conception Cheatle agrees, but with two additions, namely, the immediate exudation of plasma and a limited emigration of red and white cor-Upon the resolution of these changes the process stops. Inflammation, therefore, forms only one of the effects that may occur after injury The nature, degree, and duration of the injury induce much more vast and complicated events which should not be included in inflammation. Infection and its consequences immunity and infection, the normal growth of tis sues, the repair of tissues, and the formation of neoplasms have become separate problems, and yet they are being described at present in the one inextricable tangle of "inflammation." When one cell begins to divide into two cells a fresh element has been established and, although it may be the effect of the injury, it is not necessarily the effect of inflammation. Going more into detail, Cheatle describes the successive microscopic pictures in the repair of tissues (bone and arteries), in the formation of fibro-adenomata and papillomata of the breast and in local abscess formation, showing that these processes are so complicated and controlled (irregularly controlled in fibro-adenomata and papillomata) that they cannot be considered to be a part of an inflammatory process. In studying the local aspects of infection, subcutaneous tissues were inoculated with Staphylococcus aureus, in sufficient dosage to cause localized abscess, and then examined microscopically during a period of ten days. The successive events in the formation of an abscess were found to be (1) death of tissue with which the infecting agents come in contact, (2) tremendous emigration of polynuclear leucocytes, (3) emigration of lymphocytes, and (4) hyperplasia of the normal strands of connective tissue. The emigration of leucocytes in a suppurating process may not be the same as in inflammation produced by mechanical injury. In fact, the whole of the first part of the formation of an abscess may be considered as concerned with immunity rather than with inflammation. Microorganisms at first multiply and are mixed, with no arrangement in the lesion. By the seventh day a definite arrangement has occurred; a dense mass of microorganisms completely encircles the abscess cavity in the form of a ring. While it is impossible to explain this, nevertheless it undoubtedly has something to do with the establishment of immunity. Again, in the development of hyperplasia of the connective tissue during abscess formation, the establishment of immunity transcends in importance any concurrent process of inflammation.—Surgery, Gynecology and Obstetrics, February 15, 1933, lvi, 2A.

The Etiology of Heart Disease.-Julian E. Gammon states that the great majority of patients who seek advice regarding their hearts have funetional heart disorders, such as systolic murmur or a rumbling murmur and snapping first sound, due to vibration of the thin chest wall under the stethoscope as a result of a forceful apex beat. During the World War many thousands of overaeting hearts were wrongfully diagnosed mitral stenosis, hyperthyroidism, or myocarditis, when they had the condition which came to be known as "effort syndrome." A reflex angina may have its eause in the gall-bladder, as in a case cited by the author, in which after cholecystectomy the heart symptoms subsided and the patient was well five years later. In congenital heart disease the factors involved are embryological maldevelopment and inflammatory reactions of uncertain eause. The most frequent causes of chronic organic heart disease are rheumatic fever, syphilis, vascular hypertension, arteriosclerosis, and senility. Rheumatic fever is the most common cause of mitral stenosis and aortic insufficiency in children. Congenital syphilis of the heart is not infrequent, and the most characteristic picture of the disease, sometimes called tiger heart, is due to arteritis and extensive necrosis of the heart muscle. Bacterial infectious diseases such as pneumonia, scarlet fever, diphtheria, typhoid fever, and sepsis with marked toxemia may produce acute myocardial degeneration and even toxic death. Acute and subacute bacterial endocarditis is most frequently a part of general bacterial sepsis. Purulent pericarditis is likewise a part of general sepsis. Fibrinous pericarditis is observed in the terminal stages of nephritis and leucemia. culosis often causes pericarditis. Physiologists have demonstrated that efficient cardiac function is dependent upon adequate supplies of glycogen and oxygen, and that insulin and glucose plus oxygen are necessary in maintaining an adequate glycogen supply. Defective glycogen metabolism may be due to anoxemia as in (1) congenital heart disease, (2) respiratory disease causing inadequate lung ventilation, (3) impoverished blood in severe anemia, (4) insufficient oxygen saturation as in carbon monoxide poisoning, (5) total cessation of oxygenation as in cyanide poisoning, (6) inability of an adequate blood supply to reach the heart muscle on account of coronary disease. Defective glycogen metabolism may also be due to thyrotoxicosis. - Southern Medical Journal. March, 1933, xxvi, 3,

Spasmodic Torticollis: Its Etiology and Treatment.—After reviewing various theories as to the etiology of spasmodic torticollis, R. Glen Spurling and Franklin Jelsma conclude that we know next to nothing of what causes the disease. They were able to find only one record of an autopsy on a typical case. In this case there

were degenerative changes involving the posterior column of the cervical cord. They add, however, some evidence in support of the infectious theory. In one of their eases coming to autopsy there was definite evidence of an old inflammatory lesion involving the pia-arachnoid of the cervical cord and the brain stem. The clinical history in this case failed to disclose a former illness which might have been responsible for these findings. In a second case there was a history of epidemic encephalitis four years prior to the onset of torticollis, but at operation no evidence of a former inflammatory lesion of the meninges over the cervical cord or brain stem was found. Since all of the muscles of the neck are involved in severe cases, nothing short of radical operation will relieve the symptoms. The Keen operation forms the basis of the treatment now generally employed. This eonsists in bilateral section of the first three cervical nerves and the spinal accessory nerve in the neek. McKenzie (1924) advocated the intradural section of the first, second and third cervical nerves and the spinal accessory nerve on one side. The authors believe that the operation can be performed safely by division of the first three cervical anterior and posterior roots and the spinal portion of the accessory nerve intradurally. It is unnecessary to remove a part of the occipital bone as originally advised by McKenzie in order to section the accessory nerve. It can be divided easily through the dural incision at the level of the foramen magnum. The incision is made in the midline from the occipital protuberance to the spinous process of the fifth cervical vertebra, the laminae of the upper three cervical vertebrae are removed, and the dura opened in the midline over the three eervical segments and up to the rim of the foramen magnum. The posterior and anterior roots are now identified and sectioned, and then the spinal accessory nerve bilaterally. cutting this nerve silver clips are applied to inelude the artery as well as the nerve trunk, thus avoiding troublesome bleeding. No restraining dressing is applied, but for two days the patient's head is kept immobilized with sand bags. Convalescence in two cases treated by this method has been rapid and uneventful. The authors believe this procedure is simpler than the Finney (1925) operation and that there is less liklihood of missing important nerve roots.-Southern Medical Journal, March, 1933, xxvi, 3.

The Emergency Treatment of Some Prevalent Types of Acute Poisoning.—Sir William Willcox reminds the physician that, when called to a case of acute poisoning, he should always carry with him the necessary appliances and remedies for emergency treatment: For example, a stomach tube, a suitable gag and tongue forceps, as these may be required in comatose cases; potassium permanganate crystals, stimulant and antidotal remedies for hypodermic use, such as caf-

feine-sodium salicylate, camphor in oil and ether, strychnine, atropine, morphine, pilocarpine and coramine, calcium carbonate, calcium hydrate, sodium bicarbonate, and magnesium carbonate. He should also carry with him a suitable mouthpiece with valve and rubber bag and tubing for administering oxygen or oxygen with carbon dioxide. When a poison has been taken by mouth the first thing to do is to thoroughly wash out the stomach with warm water until the washings come away clear. Gastric lavage usually does much good even if the poison has been taken three or four hours previously. Colon lavage, using about three pints of liquid slowly introduced with funnel and tube, is of value. When a poison has been administered by hypodermic injection shortly before, cupping may be applied at the site of the injection. In poisoning by gases, such as carbon monoxide gas and by poisonous vapors such as chloroform, its removal is greatly assisted by the administration of oxygen with 5 to 7 per cent of carbon dioxide. Among the useful chemical antidotes, sodium bicarbonate is indicated for corrosive mineral acids, citric acid or tartaric acid for the caustic alkalies, lime water and calcium carbonate for oxalic acid or salts of lemon, and lime water for lysol or carbolic acid poisoning. Permanganate of potassium in weak solution, or hydrogen peroxide well diluted are indicated in alkaloidal poisoning, such as morphine, cocaine, atropine, hyoscine, phosphorus, and possibly for prussic acid or potassium cyanide poisoning. Among the physiological antidotes (remedies which have an opposite physiological action to that of the poisonous agent) pilocarpine, morphine, and eserine hypodermically have an antidotal effect in poisoning by atropine or the belladonna alkaloids. Chloral and bromide in large doses by mouth counteract the effect of strychnine.

The excretion of absorbed poison is promoted by caffeine-sodium salicylate, 2 grains hypodermically, by hot coffee and diuretic drinks. Poisoning by barbituric acid compounds is becoming increasingly frequent. These compounds are used all too frequently as ordinary hypnotics when no hypnotic is needed or when aspirin or a small dose of bromide would be adequate. A new treatment for "veronal pneumonia," which the author has used with success in several cases, is lumbar puncture. About 30 c.c. of cerebrospinal fluid are drawn off and this may be repeated in twelve hours if required. Suppression of urine due to renal necrosis may occur in poisoning by menbutal, amytal, or pernocton. This complication is generally fatal. The treatment is lumbar puncture followed by measures to promote renal excretion, such as caffeine-sodium salicylate, hot coffee, alkaline drinks, and glucose given by the mouth or subcutaneously.-Abstracted from the Practitioner, March, 1933, cxxx, 777.

The Treatment of Acute Cardiac Failure.-Carey F. Coombs says that in considering the failing heart the tendency is to transfer the emphasis from structure to function; for this reason circulatory failure now engrosses attention. Acute cardiac failure may be auricular, auriculo-ventricular, or ventricular, the last being the most important. In the treatment of all three types the first essential is rest in bed in order to bring the cardiac load to the lowest level compatible with This means lying flat in one case, sitting up in another. In the first case the ventricular wall is so weak that its work of getting a sufficient supply of blood to the brain must be reduced to the minimum. In the second case the work is that of collecting the venous blood and distributing the arterial blood when the pumping action of the diaphragm is given its fullest scope; this is served best by a sitting position. The means adopted to encourage the outflow of water from the body, such as diuresis, are in reality efforts to decrease the load of the heart. This is one of the ways in which digitalis rests the heart. Opium is valuable for the same reason. Nitrites, caffeine, diuretin, and the like undoubtedly lighten the cardiac load by dilating the coronary arteries. In myocardial failure due to the acute infections, pulse pressure is a reliable index as to the severity of the condition. Here antitoxin in diphtheria and the salicylates in rheumatic cases must be withheld. It is wiser to give saline and glucose by rectum rather than by mouth, and thus to avoid the risk of strain by vomiting. Digitalis should not be given by mouth. Strophanthin, intravenously, is the best means of securing a digitalis effect; not more than 1/200 of a grain should be given to a child of 12. If the systolic blood pressure falls dangerously low, pituitrin, ephedrine, or adrenaline may be indicated. Cardiac stimulants and tonics are best avoided, unless auricular fibrillation or auricular flutter is present. With either of these conditions the rule is six weeks in bed and six weeks of further rest. During the latter period caffeine, diuretin, or lacarnol may help to restore the coronary circulation. Ir auricular fibrillation the urgent and immediat need is for digitalis (standardized tincture). 1 drachm at first, followed by 1/2 drachm at fourhourly intervals, until 4 drachms have been taken. If vomiting is severe strophanthin may be substituted, 1/100 of a grain for the average adult, but not immediately after massive digitalis administration. When the patient is out of immediate danger, quinidine may be given tentatively. Syncopal attacks are treated preferably with atropine, at least 1/100 of a grain, repeated in an hour if there is no relief. In ventricular failure threatened asphyxia is easily relieved by 5 to 10 minims of adrenaline 1:000. In suffocative edema of the lungs, the treatment is 1/3 of a grain of morphine, with 1/100 of a grain of atropine. Practitioner. March. 1933. exxx, 777.

LEGAL

HOSPITALS-CONDITIONS ATTACHED TO TESTAMENTARY GIFT HELD INVALID

By LORENZ J. BROSNAN, ESQ. Counsel, Medical Society of the State of New York.

Of general interest to the medical profession is the decision of one of the Surrogates of New York County in a ease recently before him for decision. A man set up in his will a trust for the benefit of his sister. Upon her death the will provided that the corpus of the trust should be divided into parts, and the income from each part should be paid to a certain designated charitable institution under certain conditions which we shall hereafter discuss at length. Two of the said institutions were wellknown hospitals.

Upon the sister's death, there arose in an accounting proceeding a question as to the validity of a clause in the testator's will which

read as follows:

"FOURTH: Each and every one of the Trusts created after the death of my sister, for the seven respective institutions set forth in the 'Third' Clause of this, my Last Will and Testament, is created upon the following terms and conditions, namely: That each such institution (in case it shall be one in which physicians shall practice at any time) shall make a binding rule to the effect that any and all physicians at any time practicing for remuneration. in the said respective institutions shall be required to and shall pay toward the maintenance and sup-port of the said institution a sum of money equal to 10 per cent of the gross fees which shall at any time be received by such physicians respectively for serv-ices performed by them in the said institutions. In the event that any one of the said institutions shall refuse to make such a binding rule or after having made such a binding rule shall thereafter abrogate the same or neglect to enforce it, then and in that the same of neglect to entorice it, then and it that event the trust so created shall cease to operate and the capital of the trust created for the benefit of such institution shall thereupon be turned over by my said trustee to the Salvation Army. My said trustee, however, shall be thoroughly protected as regards any payment made to any one of the said seven institutions until such time as it shall have actual knowledge that any one or more of the said seven institutions is not enforcing the rule above set forth covering the contribution by physicians."

The hospitals appeared in the proceeding and took the position that the conditions attached to the gift in the clause above quoted were unreasonable and against public policy and, hence, invalid and void. They sought to obtain a ruling from the Surrogate to the effect that the hospitals might benefit under the trust without being subjected to the conditions that had been written into the will.

At the hearing before the Surrogate, a number of prominent physicians testified that these

į

conditions were violative of the Code of Ethics governing their profession and expressed the opinion that harmful results would follow if the court attempted to earry out the wishes of the testator. It was argued on behalf of the hospitals:

(1) That the physicians connected with the hospitals would probably relieve themselves of the burden imposed by the will, by raising their fees and making their patients involun-

tary contributors to the hospitals.

(2) That no physician of standing could or would submit to the rule prescribed by the trust, and that the physician's high regard for his reputation would necessarily result in his withdrawing from the hospital staff of a hospital having in effect such a rule as that contemplated by the testator.

(3) That the inevitable result of the enforeement of this rule would be that the institutions would lose their standing in the community, with a resultant falling off in donations, thus rendering the institutions

unable to earry on their charities.

(4) That the rule in question was in direct conflict with Article 32 of the Principles of Professional Conduct of the Medical Society of the State of New York.

The Surrogate in a very well-considered opinion ruled to the effect that the conditions attached to the trusts were invalid and void, and directed that the gifts to the institutions should be carried out as if the conditions attached to them had been omitted by the draftsman of the will. The Surrogate found that the evils described in the arguments advanced by counsel for the hospitals would undoubtedly result, and that the conditions imposed were against public policy and were unreasonable, impossible of performance and void. In part the court said:

"It is immaterial whether the division of medical fees occurs between a physician and a layman, or a physician and a physician in cases prohibited by the canons of chics, or, as is the situation here, between a physician and a hospital. In the latter case an outside agency participates financially in the compensation of the physician liceused by the state to practice medicine. Inevitably such a method of division would lead to deterioration in the medical staffs of hospitals with attendant injury to the public. It would likewise subject some physicians to the temptation of overcharging their patients in order to

meet the requirements of the hospital rule. It is conceded even by the Salvation Army, the alternative beneficiary, which would take in the event that the disputed gifts were ineffectual, that no reputable hospital in the United States has applied the rule of division of fees or compulsory charity sought to be enforced by the testator in his will. In the case of one of the hospitals which is a benchiciary here, it has been established that 280 physicians and surgeons give their services free for the treatment of indigent patients. At the same time most of them use the facilities of the hospital for treatments of or operations upon patients who can afford to pay. The revenue derived from the renting of the rooms, operating rooms and other facilities enables the institutions to support to a large extent, its charitable activities in the treatment of free patients in dispensaries or in the hospital wards. It is argued that serious difficulty would arise in the ascertainment, under the terms of the will, of the compensation received by the physician from paying patients for the services rendered in the hospital and those rendered before or after hospital treatment. It is urged that it would be impossible to properly allocate these charges so as to compute the basis upon which the 10 per cent is to be determined. Certainly there would be a practical difficulty in this process. Ordinarily the difficulty in enforcing a condition might not be a ground for a determination of invalidity, but where, as here, it is mingled with a requirement that is unreasonable, unethical and in violation of public policy, the court cannot sustain it.

The Surrogate suggested in his argument an interesting parallel in an assumed case. He stated a supposed case of a trust in favor of a

Bar Association, conditioned upon a requirement that all lawyers who used its library in connection with any of their cases should turn over to the Bar Association a percentage of the fees received from all cases worked on in the said library. Such a condition, the Surrogate contended, would be both unethical and illogical, and no one would dispute its invalidity.

The Surrogate's opinion continued:

"Similarly, the attempt of the testator here to fasten a new custom upon the medical profession is equally obnoxious and contrary to the best interests of the community. The charitable purpose of the testator is obvious and his intention to benefit the hospitals which he selected clear. The difficulty, however, that he attempted to impose a rule of compulsory charitable contributions upon others. However, the method which he devised to compel the physicians to be charitable is bad and not entitled to legal recognition."

The decision of the learned Surrogate is a most salutary one. The Surrogate saw clearly the evils resulting from upholding the trust as written by the testator. Public policy would seem to dictate that no one shall have a right to attach to a donation to a hospital conditions which would force its physicians to violate the ethics of their profession. It is to be hoped that if an appeal is taken, the decision of the Surrogate will be upheld by the higher courts.

PORTION OF PLACENTA RETAINED AFTER DELIVERY

A doctor who specializes in gynecology was consulted by a young woman whom he had previously attended in childbirth with respect to her condition of pregnancy. She was at the first consultation about two months pregnant and her condition was normal. He made arrangements to deliver her and give her postnatal care and treatment at a private hospital operated by him. He saw her monthly, examining her from time to time and taking various urine tests and blood counts. She finally entered the hospital, and he examined her and found a dilation equivalent to two fingers, and that part of the placenta was protruding out preceding the head of the infant. After carefully sterilizing his hands and putting on rubber gloves, he pushed back the placenta and delivered the child without difficulty. The child was normal. There was considerable hemorrhage but upon the administration of hypodermic injections it stopped in satisfactory time. He then carefully removed the placenta, which he took out in pieces as it was torn. The patient was put in bed and had an uneventful recovery. The ninth day she got out of bed but after she had been up for a time she developed a slight flow. The doctor ordered her back in bed for two more days and from that time she had no further discharge although she remained at the hospital for a few days more. During all her stay at the hospital the doctor saw her daily. Subsequent to her discharge the doctor never saw her again.

The claim was made that subsequently some other doctor removed a further portion of placenta which the doctor who delivered her had not found, and a suit was brought charging him with negligent treatment. The plaintiff claimed that four days after she left the hospital she underwent an operation to remove the retained placenta. She claimed as permanent injuries that she suffered from a fallen womb, inability to bear children, inability to perform her sexual duties, improper menstruation and nervousness.

The case was tried before a judge and jury and at the close of the testimony, the court, on motion of the defendant's counsel, ruled that the plaintiff had failed to prove negligent or improper treatment on the part of the doctor, and dismissed the

complaint.

LLG 1I

A general practitioner was consulted by a married wom in about 35 years of age, who complanted of back ache and vaginal discharge. He put her on his table and examined her. He found that she suffered from a badly eroded cervix which was bleeding and enlarged. The uterns was retroverted and irregular masses were de-There was a very foul discharge doctor explained to the woman that in order to he relieved of her condition she should submit to The operation was not consented an operation to for some months. During the interim the doctor was consulted several times and on each occasion the patient's cervix was eleaned out and argyrol was applied. Finally she consented to an operation, and at her request the general practitioner recommended a surgeon to her who un-His examination dertook the necessary work confirmed the diagnosis previously made. A com-

plete panhysterectomy was performed upon the patient under a spinal anosthetic. Exploration

showed that the appendix was influined the tubes and ovaries were inflamed and enlarged and adherent to the neighboring organs and intestines. Tumors were found in the interns. The complete pathysterectomy was performed and the appendix also removed. The incision was sutured up without a drain and the patient's recovery at the hospital was uneventful.

Sometime thereafter an action was brought against both of the dectors charging inalpractice. The complaint included allegations that the decidants had indertaken an operation which was minor in nature. The charge was made that due to their negligence the operation which was performed was much more extensive than intended. The case came on for trial some four years later and when it was called the plinitiff's attorney failed to appear to proceed. The attorney for the doctors made a motion for judgment of dismissal, which was granted terminating the initter thereby.

PLASTIC OPERATION UPON THE NOSE

A doctor who specializes in nose and throat work and plastic surgery was consulted by a middle aged man who complained of a nasal de-The doctor found upon examination that he had an oversized nasal deformity with a pendulous septum Arrangements were made for an operation, which was performed at a sanitarium, under a local anesthesia. The doctor incised from the inside of the nose, on both sides, and separated the skin from the underlying boney structure He then removed the oversized boney and cartillaginous portion of the back of the He shortened the septum and the lateral side of the nose and narrowed the nose at the tip end and bridge He then firmly sutured up the inside and packed the nostrils The operation was performed entirely from the inside without disturbing the skin on the outer portion of The patient remained in the sanitarium for a couple of days and then went home in an excellent condition. Following this the patient came to the doctor's office for removal of In a few days the nosc was healed without infection A few weeks after the operation he came to the doctor's office and examination showed that a condition of active acne had developed on the left side of the tip of the nose He punctured the pimples and removed a small amount of pus. When the patient again re-

turned the pimples had healed and two small sears were noticeable in their place. These scars were similar to other acid scars that were all over the patient's face before the operation. The doctor administered a local anesthesia and incised and cut out the two scars. A few weeks later the man returned complaining of lines where the sears had been. The scars at that time were healed. The doctor refused to do any more operating. A considerable period of time later the patient again came back to the surgeon, and requested an operation. His nose was excellent, but he still had the two lines. The doctor declined to operate and the min left.

The next thing heard of the matter was when a summons was served upon the doctor. The patient's complaint charged that the operations were so negligently performed that certain large ugly scars remained on the plaintift's face. The complaint made no allegation of negligence at a later date than about two years and eleven months prior to the date the suit was commenced.

The defendant's attorney made an application to the Court at a Special Term for an order directing judgment of dismissal on the grounds that the action had not been brought timely under the statute of limitations. The plaintiff's attorney realized the ment of the application and consented to discontinue the action by stipulation.

NEWS NOTES

MEETING ON ASPHYXIAL DEATH

An all-day conference on the subject of Asphyxial Death will be held on Wednesday, May 24, 1933, in the building of the New York Academy of Medicine. This meeting has been arranged by the Society for the Prevention of Asphyxial Death which was organized in February, 1933, for the purpose of promoting a knowledge of the newer methods of treating asphyxia by physicians, and of securing their adoption by utility companies, ambulance services, and other organizations interested in artificial respiration. The application of the newer methods to resuscitation was demonstrated at the meeting of the Medical Society of the State of New York, on May 25, 1932, in Buffalo, by Dr. P. J. Flagg, whose paper was published in this Journal of March 15, 1933, page 395.

The conference on May 24 will be held in two sessions,—the morning one being largely on the economic and social aspects of resuscitation, and the afternoon on its medical phases. Physicians will find the afternoon session of special interest. The speakers at the confer-

ence are as follows:

1. Vital Statistics and Asphyxia. Dr. Shirley W. Wynne, Commissioner of Health, New York City.

2. Medical Examiners' Findings Relative to

Asphyxial Death: Dr. Harrison P. Martland, Medical Examiner, Essex County, New Jersey.

3. The Economic Aspects of Asphyxial Death: Albert W. Whitney, National Bureau of Casualty and Surety Underwriters, New York City.

4. First-Aid Methods of Resuscitation in the Police Department. Motion Pictures. Dr. Daniel J. Donovan, Chief Surgeon, Police Department, New York City.

5. Fundamentals of Peroral Endoscopy: Dr. Chevalier Jackson, Philadelphia, Pa.

6. Fundamentals of Gas Therapy as Related to the Use of Oxygen and CO₂: Dr. Yandell Henderson, Yale University Medical School.

7. The Practical Application of Laryngoscopy and Gas Therapy in the Treatment of the Asphyxiated. Dr. Edmund B. Piper, Obstetrical Department, University of Pennsylvania Medical School.

8. Principles and Applications of Differential Pressures:—(Negative Pressure Cabinet). Dr. P. N. Coryllos, Cornell University Medical College.

9. Practical Application to the Hospital and the Public: Dr. John F. McGrath, New York

City.

HERKIMER COUNTY

A meeting of the Herkimer County Medical Society was held in Herkimer at 3:00 in the afternoon on April 11th. Twenty-eight members were present.

A resolution was adopted to send a letter to the Superintendent of the Utica State Hospital requesting him to notify, by mail, the physicians on the committing commission, when an inmate or patient is paroled or discharged from the institution. Some unpleasant features have occurred when a patient has been paroled or escaped from such an institution and returned to his home town. Such patients quite frequently have a real or fanciful grievance against the physicians making the commitment.

The existing executive committee was, instructed to meet and select a list of names to present to the County Board of Supervisors for the selection of a member of the County Poor commission.

The T.E.R.A. resolutions were read and adopted to apply to the care of indigents within the county. No physician is to do charity work for any city or village under contract.

After the business session the first of a series of six postgraduate lectures was given by Dr. Greene of the University of Buffalo Medical School. The topic was "Angina Pectoris, and Coronary Occlusion." Dr. Greene presented this subject in an interesting manner and elicted much discussion. We are to have five more lectures in the next five weeks, all on some form of heart disorders.

The lecturers are from the University of Buffalo. F. C. Sabin,

Chairman of Publicity Committee.

WASHINGTON COUNTY

A special meeting of the Medical Society of the County of Washington was held in Fort Edward, N Y, at 3 30 P M on March 28, 1933, with 20 members present, as follows Doctors Macarthur, Preseott, Borrowman, Hultz, Farrell, Rogers, Leonard, Holmes, Park, LaGrange, Pashley, Jr, Bennett, Banker, Tillotson, Wlute, Falkenbury, Joshn Orton, Casey and Cuthbert The object of the meeting was to consider the question of nucleal care to the poor of the county

The President took up the different clauses of the rules and regulations governing medical care as published in the New York State Health News Dr Presented the matter of the treatment of veneral diseases Doctors Bennett, Rogers and Hultz, were appointed a commuttee who drew up the following resolutions

WHEREAS, the Commissioner of Public Welfare of Washington County has instituted contract medicine in the town of Whitehall, Washington Co, and in so doing his forced the physicians of that town, in their treatment of all welfare charges, to accept compensation of approximately twenty per ecut of the regular fees as established by the Washington County Medical Society; and

Whereas, this action was earried out and enforced upon the physicians of Whitehall by means of the threat to bring into the town of Whitehall a physician who was not a resident of the town or county, and to employ said physician to care for all welfare cases, and

WHEREAS, this procedure is directly contrary to the code of ethics of the American Medical Association and the Medical Society of the State of New York, and not conducte to the maintenance of cordial relations between the medical profession and the general public, be it therefore

Resolved, that we, the members of the Medical Society of the County of Washington, State of New York, go on record as condemning the action of the Commissioner of Public Welfare especially since he did not first consult the Committee on Public Relations of the Washington County Medical Society and advise them of his proposal, and be it further

Resolved, that this matter be brought to the attention of the Public Relations Committee of the State of New York and to the attention of the Micheal Society of the State of New York for their consideration

These resolutions were adopted

Dr Falkenbury moved that, with the exception of initernity eases, we reduce our bills from our regular prices for welfare eases thirty three and one-third per cent, rendering our bills in the regular prices, with the reduction for the present emergency only

This resolution was adopted

The following resolution was adopted at a later special meeting

Resolved, That home calls to Welfare Department be charged at \$2.00 and office calls at \$1.00, twenty-five cents additional for each mile covered (one way) outside the village limits. For calls between 9 P M and 7 A M the above fees shall be doubled. Maternity cases, \$25, including three post-partim calls.

S J BANKLR, M D, Secretary

RENSSELAER COUNTY

The regular monthly meeting of the Medical Society of the County of Rensselaer was held on the evening of Tuesday, April 11, in the Health Center, with the President, Dr W W St John in the chair The scientific program consisted of a symposium on eancer, and was as follows

"The Relation of the General Praetitioner to the Cancer Problem," Dr John M Swan of Rochester

"The Relation of the Pathologist to the Cancer Problem," Dr Steplien H Curtis

"The Relation of the Surgeon to the Cancer Problem," Dr Peter L Harvie and Dr E F Connaily "The Relation of Pathology to Surgery in the Caneer Problem," Dr. Russell S. Fergison of New York

"The Significance of Radio Sensitivity," Dr Ellis Kellert of Scheneetady

"The Relation of Radiation to the Cancer Problem," Dr H W Carey, Troy, and Dr A F Holding of Albany

Each speaker limited his paper to ten minutes, and active discussion followed the concluding number of the symposium

BOOK REVIEWS

COLONIC IRRIGATION. By W. KERR RUSSELL, M.D. Octavo of 191 pages, illustrated. Baltimore, Williams & Wilkins Company, (William Wood & Company), 1932. Cloth, \$3.00.

With the great increase in the popularity of this procedure with patients and its widespread administration by laymen, this study from a physiological and anatomical standpoint by a qualified physician is timely. The willingness of lay agencies to irrigate the colous of all who apply for it without adequate diagnostic preliminaries has done much to bring this valuable therapeutic method into disrepute in the United States. "Colon filling stations" so named by Dr. Basler, appear on every hand. With proper regard for the scientific medical principles involved this form of treatment is valuable.

Dr. Russell has presented the result of his study simply and directly, comparing the advantages of the methods with which he is familiar. He seems to prefer the Borosini Treatment, although in this country the large colon tube with a too and fro current is more favored. No adequate justification for the elaborate "subaqueous intestinal bath" is supplied. Perhaps there is none.

Many conditions are mentioned in which colonic lavage is beneficial and many useful formulae are given.

Because colon therapy lends itself so easily to quackery it should receive more serious attention from responsible clinicians.

This little book supplies many facts which should be helpful in such a study.

HENRY F. KRAMER.

PARENTS AND SEX EDUCATION. By BENJAMIN C. GRUEN-BERG, M.D. Third Edition, 12mo of 112 pages. New York, The Viking Press, 1932. Cloth, \$1.00.

The author maintains that ignorance on sex matters is responsible for many of our social woes, such as, divorces, illegitimacy, prostitution, sexual perversion, delinquency, and anxiety neuroses. That these conditions are even more prevalent in recent years in spite of increasing sex education he does not mention.

However necessary some knowledge of sex may be, one may not accept the author's contention that the preschool clild should be taught the names of the different sex organs, and that it should be given frequent opportunity to see the unclothed body of the opposite sex in both young and old so as to reduce the embarrassment and euriosity which would necessarily follow when such observations were inadvertently brought to its attention. In other words, the author is a confirmed nudist representing the last word in social faddism. The reader may wonder whether the author is a parent, and what success he has had with his own children.

The care of the child is not based on any uniform plan, but on methods which become more and more complicated and discordant with each additional publication on that subject. After reading some of these books one realizes more and more that common-sense and sympathy are more important for the ueeds of the individual child than the stereotyped directions of an impractical author.

This book bears the endorsement of the American Social Hygiene Association and the Child Study Association of America.

EMANUEL KRIMSKY.

CHILDREN'S TONSILS IN OR OLDT. By ALBERT D. KAISER, M.D. Octavo of 307 pages, illustrated. Philadelphia, J. B. Lippincott Company [c. 1932]. Cloth, \$5,00. For more than twenty years it has been increasingly emphasized that tonsils must come out. That the theory of focal infection has not been very dependable in its practical results has only recently been brought to our attention and largely through the intensive investigation by Kaiser. In this book he tells us in a conclusive manner what may be expected from a tonsil operation. These conclusions are based on careful observations of thousands of children. This book should serve indispensably in impressing on physicians that tonsils should not be removed nuless there is a definite indication for their removal; that wholesale removal of tonsils in hospitals should be stopped; and that the family physician or pediatrist should assume the responsibility of deciding when an operation is necessary. That the results of tonsil operations have not been entirely satisfactory is being nore and nore brought to our attention by a number of workers.

Doctor Kaiser has made the tonsil problem a complicated issue and if we follow suit in his researches the patient will no doubt be the beneficiary.

EMANUEL KRIMSKY,

Oral Spirochetes. By David T. Smith, M.D. Octavo of 243 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1932. Cloth, \$4.50.

This book represents an enormous amount of investigation with the fusiform bacilli and spirochete. It is written in a very interesting manner, lucid and clear. The literature has been gone over in detail. The role of insospirochetes in local and focal infection is discussed thoroughly. The reviewer, however, is left with the impression that the pathogenecity of these organisms, has perlaps, been somewhat overemphasized. Naturally, a goodly portion of text, is devoted to the mouth and teeth, but many chapters describe spirochetal infections of the various organs in the body, and the final chapter describes such infection in other animals. The book is well worth reading and should serve as an incentive to stimulate anaerobic cultural studies, where only acrobic cultures are now done.

AN INDEX OF PROGNOSIS AND END-RESULTS OF TREAT-MENT. Edited by A. RENDLE SHORT, M.D. Fourth Edition. Royal octavo of 599 pages, illustrated. Baltimore, Williams & Wilkins Company (William Wood & Company), 1932. Cloth, \$12,00.

The Index of Prognosis is a volume of 900-odd pages, constituting the third of a series by British writers, the other two volumes being the Index of Differential Diagnosis, and the Index of Treatment. The list of contributors includes such well-known names as Sir Humphrey D. Rolleston, Poynton, Coombs, Gnlland, and many others. The subjects treated are alphabetically arranged, from abdominal injuries to yellow fever. The papers are for the most part discussions on the course and outcome of various diseases, written from the standpoint of the broad clinical experience of the authors, rather than the statistical studies to which we are growing accustomed in this country. Such an outlook is more valuable in judging the chances of any individual patient than the method of cataloging his diagnosis and determining the mortality percentage of his particular pigeon inhing the mortality percentage of his particular pigeon look, important as the statistical method is to health officers and actuaries. There is much clinical wisson in the Index to Prognosis.

HEMO CYTO-SOL

When anemia follows the operation intensive iron and arsenic medication may be indicated. To produce rapid regeneration of red blood corpuscles and increase of hemoglobin, the preparation used should be adapted to intramuscular injection.

Hemo-Cyto-Sol contains colloidal iron, anhydrous alkaline cacodylates and a small amount of strychnine sulphate in a specially prepared isotonic solution.

Each Ampoule Contains the following:

Indicated as a blood regenerator in all anemic conditions

It is generally given intramuscularly, but may be employed intravenously in cases of great urgency.

Supplied in boxes of 12 ampoules, each containing 5 c.c.

Why not write for a sample?

medical care until the patient recovers. If found unworthy of public relief the doctor would treat the case as any other private patient. At the end of the month he sends an itemized statement to the Auditing Committee of the Academy. This bill for service is rendered at the usual prices for such service in this city."

The doctors' bills for the month of January exceeded the estimate, according to Dr. Knapp, who said:

"During the month of January we had some \$4,600 worth of bills and we had less than \$1,000 with which to pay them. We have a contract with one or two of the surrounding towns, from one of which we get \$100 and from another \$75, I think. We paid twenty cents on the dollar during January. We are checking on this thing because we want to know what the indigent costs in our county are going to be. We never were able to get accurate figures on it. We are paying an accountant to run the accounts of the association, and in another year we will be able to stand our ground and tell the supervisors or city commission what sort of contract we are willing to make with them. At the present time we are not kicking. A \$3.00 call we make for sixty cents but this is going to give us some facts on which to base future work."

The following subjects were also discussed at considerable length:

Radio broadcasting Health Insurance Challenge to the county society Mobilized forces

Dr. Olin West, Secretary of the American Medical Association, said, in discussing the independence and leadership of the county society:

"The local County Medical Society must study its own problems, secure all the information that it can of a general nature, in the hope that it may find some information that will immediately apply to its particular problems, and deal with them to the best possible advantage, always with the earnest conviction that they must be dealt with in a manner that will first serve the public interest and the interests of the individual patients."

SECRETARIES' CONFERENCE IN MINNESOTA

The April number of Minnesota Medicine contains the following description of the conference of County Secretaries which was held in St Paul on February 18:

(Continued on page 669-adv. xiii)

(Continued from page 668-adv. rii)

"The question of state dues received considertable attention. Dr. Savage of St. Paul, one of the state enuncillors, outlined the activities and the accomplishments of the State Society and explained the budget requirements for 1933. While this budget includes some economies, it does not contemplate a reduction of the present dues. In spite of this convincing recital and the assurance that vital activities could not be maintained on cless income, a very determined effort was made by the representatives of two county societies to siving the sentiment of the meeting toward a reduction. The debate became rather noisy and bitter, but the overwhelming sentiment as expressed by speeches and ballnt seemed to be that while the society as a whole would welcome the assurance of its officers that its dues could be reduced without harm to its important activities. since that assurance was not forthcoming and most obviously could not be given, state dues should be maintained as they are. As expressed 1 by one member—if the present and contemplated activities of the State Society cost two or three z times as much as they have they would still be t worth it.

"Having safely passed this hurdle, the meeting next viewed with horror the growing incidence of malpractice suits and the imminent danger of a i' rise of insurance rates. Legal representatives from various companies outlined the causes. Greater activity on the part of hungry attorneys explains the increased incidence, and growing resentment of the average juror toward any organization with money explains the larger verdicts. For the most part, malpractice suits grow out of eareless or vindictive comments made by physicians themselves about the work of others. It was suggested that the Golden Rule might be applied here, for without the assistance of physicians no malpractice suit could be successfully prosecuted Physiciaus were warned never to belittle the work of a fellow practitioner in the presence of the patient.

"The various methods of caring for the indigent by county societies were discussed. Theodore Sweetser outlined the various plans now contemplated or in operation. Dr. Collins of Duluth described a program practically adopted in St. Louis County whereby a lump sum was paid to the county society. This was pro-rated to the members contributing the service on the basis of the number of calls or office consultations rendered. Mr. George B. Larson, secretary of the Polk County Medical Society of Wisconsin, described a plan which has been in operation for some time. In this admittedly successful scheme, the members contribute the service and the lump sum received from the county carries on the activities of the society and pays the state dues. It was pointed out that no one plan meets the requirements of all counties and that each county

society must study its own peculiar problem and

model its system accordingly.

"Of such value did the members of this society regard the present radio broadcasts sponsored by the state society that Dr. William A. O'Brien in his usual lucid and fluent style told how to build interesting and worthwhile society programs. The text of his theme was that the subject was more important than the man and should be chosen first, and afterward the best speaker.

"The afternoon conference was devoted to a consideration of the effect of workmen's compensation on medical practice and to some of the 1933 legislative problems. A representative of one of the large insurance companies handling compensation insurance presented the insurance side of the controversy, while Dr. C. B. Wright and Dr. J. M. Hynes presented the physicians' point of view.

"Dr. Herman Johnson discussed some of the bills to be presented to the 1933 legislature which

have a direct effect on medical practice. There was the usual chiropractors' effort to get out from under the basic science law. The naturo paths surprised everyone by securing the services of ex-Judge of the Supreme Court Hallam to represent them. Dr. Johnson urged everyone to communicate immediately with their representatives in an effort to offset the considerable influence of Judge Hallam.

"Whereas we have already disclaimed any responsibility for having failed to dispose of any momentous question, the meeting was eminently worth while in promoting an understanding the other fellow's problem and in developing united front as an organized society. The grow ing threats to the continued enjoyment of the practice of medicine call for a unity of effort greater than ever before achieved. The relative youthfulness of the majority of the secretarie and the keen interest shown in economic matte suggest that these matters will continue to recei attention."

STATE AID TO COUNTIES IN TENNESSEE

The Journal of the Tennessee State Medical Association discusses state aid to counties in public health work as follows:

"Several county newspapers in the state

have criticized the members of the Medi Association for appearing before a commit of the legislature in opposition to one item

RESEARCH LABORATORY—LILLY

Physicians know the standards by which the efficacy of a good bactericidal agent should be judged and are, therefore, in position to appreciate the findings of research chemists who show that in developing such a preparation it is quite as necessary to consider the effect of the bactericide on animals and animal tissue as it is to prove that the product will destroy bacteria.

Merthiolate, a product of the Lilly Laboratories, has been shown to possess

both of these very desirable qualities. It is safe to use, does not destroy the defensive mechanism of the tissue cell, is non-irritating to tissue surfaces, and does not lose its potency in the presence of organic matter. It is an effective germicide. Combining as it does these distinguishing features, it is not surprising to learn that Merthiolate possesses marked healing properties, repeatedly verified by extensive clinical trial.

One physician with a large office practice recently remarked that since the advent of Merthiolate Tincture, an alcohol-acetone-aqueous solution containing inert coloring material, he had been using it in all minor surgical operations, which are often performed in the home and the office under conditions that leave something to be desired. Without exception, no infections of any kind had developed and he credited Merthiolate Tincture with the results obtained.

In addition to the colored tincture, Merthiolate, Lilly, is supplied by pharmacists in a variety of convenient forms, including an aqueous solution, a jelly, an ointment, and an ophthalmic ointment.—Adv.

"WHEN, AS AND IF"

The bottle-fed baby exhibits symptoms indicating partial vitamin B deficiency—described by Hoobler as (1) anorexia, (2) loss of weight, (3) spasticity of arms and legs, (4) restlessness, fretfulness, (5) pallor, low hemoglobin, etc. . . .

Dextri-Maltose with Vitamin B may be used in adequate amounts (up to 71 Chick-Roscoe units) without causing digestive disturbance. This ethically

advertised product derives its vitamin B complex from an extract of wheat germ rich in B and brewers yeast ich in G. Physicians who have attempted to make vitamin B additions to the infant's formula but who have been obliged to abandon this due to diarrheas or other unfortunate nutritional upsets, will welcome Mead's Dextri-Maltose with Vitamin B. This is a tested product with rich laboratory and clinical background and is made by Mead Johnson & Company, a house specializing in infant diet materials.

Not all infants require vitamin B supplements, but when the infant needs additional vitamin B, this product supplies it together with carbohydrate. In other cases, the carbohydrate of choice is Dextri-Maltose No. 1, 2 or 3.

APPENDICITIS. GENERAL SURVEY AND STATISTICS

By THEW WRIGHT, M D, BUFFALO, N Y.

Read before the Buffalo Surgical Society on February 18 1937 in a round table discussion on Appendicitis

THAT a disease which if promptly recognized and properly treated should be practically free from mortality nevertheless does show an annual death rate in the United States of 18 per hundred thousand, thus equiling the combined death rates from ectopic pregnancy, pyosalpinx, gall stones, surgical diseases of the pancies, spleen and thy roid, and nearly equaling that from gastric ulcer, duodenal ulcer, intestinal obstruction and gall stones, and exceeding that from measles, scarlet fever and whooping cough to gether, as well as totaling that from automobile accidents, and nearly equaling that from diabetes is a fact sufficiently striking to warrant our most serious and thoughtful consideration

Although all of its aspects are of interest and the question of diagnosis and the best methods of handling the various types and manifestations of the more advanced stages of the disease may still present some opportunity for argument, the factor of prime interest it seems to me should be what can be done to lower this death rate to the almost negligible figure where it belongs. Of the many compilations of statistics and reports which have been published it seems to me the only figure of any real value is the actual number of those who die of the disease Compilations of the mortality rate in any particular series of cases operated upon are of some interest but accurate con clusions from most of such compilations are difficult to obtain The reason for this fact is the difference in nomenclature used to describe the various types of appendicitis and the various complications which present themselves at different stages of the disease Whereas certain methods of handling the later stages of the disease may give a lower death rate than certain other methods, there is really very little difference in the statistics among operators of experience even though their methods differ, and it is not by any change in the handling of late cases that we are going to cut down appreciably the number of deaths from the disease It is only by bringing cases to operation in the earliest stages that much can be accomplished When one reviews the various sta tistical reports from different hospitals and different operators one finds oneself in such a jumble that relatively little of value is gleaned from the study The one fact which stands out clearly and undisputed and runs through all reports is that cases operated upon early, that is within the first eighteen to thenty-four hours of the disease show a mortality around one per cent Whereas cases operated later show rates from five to ten at the end of forty-eight hours or eight to twenty at the end of seventy-two hours. I think we will all agree that operation while the infection is confined to the appendix is attended by practically no mortality. If we are to stop the toll which this disease exacts it must be by means of educating both the physician and the layman to the appreciation of this fact and I would like to see our Society mangurate some movement for the education of the public in our State such as that which is being carried out in Pennsylvania.

If none but surgeons of the highest skill had operated on all the cases of appendicitis which were operated upon last year the death rate would. I believe, still be far in excess of what it should be, although considerably lower than what it was Although I am strongly opposed to having un skilled operators open the abdomen under any circumstances the mortality would be undoubtedly lower if all cases were operated during the first eighteen hours even by mediocre surgeons than would be the case if handled by the most skillful forty-eight hours later We must continue to preach early operation and no cathartics, for in spite of all that has been written the administration of castor oil is still altogether too frequent both in adults and in children, and not only are the lasty themselves guilty but, unfortunately, too many physicians still fail to recognize the danger in administering cathartics in the presence of ab dominal pain

A starthing fact about the present death rate from appendicitis in the United States is that it is almost one third higher than it was ten years ago. There must be some explanation for this and in my opinion there is a very simple one and I have before this expressed my views in print. I will quote a few paragraphs from a book which I

published several years ago in an effort to do my bit towards educating the laity.* "Because of the fact that operations performed early in an attack of acute appendicitis, as well as interval operations, and those performed for chronic appendicitis, are attended by an almost negligible mortality, the impression has arisen that operations for appendicitis are simple, and can be performed by any one who can use a surgeon's knife. It is true that operations under such circumstances are as a rule simple, and can be successfully made by operators of limited experience; but when the disease has progressed to any extent, and especially when any of the numerous complications exist, it may require the very highest degree of surgical skill and the benefit of long surgical experience to handle the case properly, and bring about its successful termination.

"The abdomen has been likened to a grab-bag; one never knows exactly what one is to find until it is opened, and no one should open it unless prepared and qualified to meet and handle properly any of the complications that may be found, or

emergencies that may arise.

"One of the three important factors in the explanation of the fact that the death rate from appendicitis is still many times higher than it should be, is that the seriousness of the operation is under-estimated, both by the laity and by many physicians, and occasional operators undertake cases that are beyond their ability to perform, and on attempting them find themselves confronted with conditions with which they cannot successfully cope.

"The actual death rate from appendicitis is higher in this country today than it was ten years ago. This can only be explained by the undeniable fact that a constantly increasing number of operators with insufficient surgical experience have been undertaking surgical procedures for which they were not adequately prepared; for, of the other two prime factors in mortality, namely: delay in operation, and the administration of cathartics, certainly the former is met with less often, while there is little reason to think that the latter is more frequent.

"The death rate among the larger clinics and hospitals does not show such increase. This does not mean that operations for appendicitis should be performed only in such centers, or by eminent or distinguished surgeons, for there are today qualified surgeons and excellent hospitals in nearly all communities. It does mean, however, that care should be exercised in selecting a competent surgeon, and that unless such care is taken, many cases will die which could and should be saved."

There is no gainsaying the fact that there are from ten to twenty operators in the United States today for every one of fifteen years ago, and unfortunately a large percentage of these operators have not had the requisite training to make them real surgeons. How else are we to explain the fact that our death rate from appendicitis is twice that of Switzerland, three times that of Germany, more than double that of England and Wales, and six times that of Italy, in which countries operating is only permitted to those who have had adequate special training in surgery and not as it is in most States of this country where the mere degree of M.D. carries with it the right to operate upon any condition regardless of the operator's ability to handle it or any special training in surgery.

It does not fall in the scope of my remarks to take up the diagnosis of the disease; that will be ably handled I know by one of the speakers who follows, but I do wish to call attention to two factors which I believe to be of importance—one is that the highest mortality rate of the disease is in children, practically fifty per cent of the reported deaths being in childhood. The disease running a more rapid course and complications being more frequent should make us most alert in our diagnosis and make us ready to operate in every case of suspected acute appendicitis in children when we cannot definitely exclude its presence. This will, of course, lead to an occasional unnecessary appendectomy but it will also save many lives which would be lost by procrastinating until the diagnosis could be unrefutably made. I have operated upon a large number of young children in which it was difficult to make an absolutely positive preoperative diagnosis but who were found to be suffering from the disease. I am myself firmly convinced that acute appendicitis is much more frequent in infancy than has been realized, the difficulty and, in some cases, the impossibility of making a positive diagnosis having misled us. The finding of an acutely inflamed appendix in cases subjected to operation upon merely a strong suspicion when the risk of operation seemed less than that of watchful waiting and the indisputable evidence of previous attacks of acute inflammation found in appendices removed from children never known to have had the discase before, has steadily strengthened this conviction. Each year, study at the operating table, in the pathological laboratory, and of the pre- and post-operative histories of my patients, has made me realize more fully that both acute and chronic appendicitis is far more common in children than it is usually thought to be; that many cases of acute and subacute appendicitis pass unrecognized and that a large number of children have suffered and are suffering from unrecognized chronic appendicitis.

The second point is the frequency with which a chronic appendicitis may exist for some time prior to an actual acute attack. So often at operation for acute inflammation we find constrictions or kinks which interfere with the emptying of the

^{* &}quot;Appendicitis," Allen Ross & Co., New York.

appendix that I believe we should urge a prophylactic appendectomy in any case in which x-ray shows an abnormal retention of barium even in the absence of other evidence of chronic appendicitis.

Chronic appendicitis is a most unfortunate term and its use has caused an endless amount of discussion and waste of words and energy because those discussing have usually been talking at cross purposes, due to the fact that neither has understood what the other has meant by the term. The suffix "itis" of course denotes the presence of an active inflammatory process, and the absence of any such process in the appendix when studied by the pathologist has led to confusion.

I am including under this term not merely the occasional cases in which a subacute or chronic inflammation does exist, but the large number of cases in which mechanical irritation either from within the appendix or its immediate neighborhood is producing ill-health. This mechanical

irritation with its consequent varied reflex manifestations may be produced by concretions within the appendix, by acute kinks due to a short or distorted meso-appendix, or by adhesions or congenial peritoneal bands, or by constrictions produced by scars resulting from previous acute inflammation. It seems to me that it must be admitted that an appendix showing any of these conditions is more liable to acute inflammation than is a normal one and, therefore, I always advise its removal.

I believe that our only hope in reducing the mortality rate of this disease lies in the education both of the laity and the physician; first to the understanding that appendicitis is absolutely a surgical disease requiring prompt operation; second that there is great danger in the administration of catharsis in the presence of abdominal pain, and third that care should be exercised in choosing the operator to whom the patient's life is to be entrusted.

DIAGNOSIS OF APPENDICITIS

By EARL P. LOTHROP, M.D., BUFFALO, N. Y.

Read before the Buffalo Surgical Society on February 18, 1932, in a round table discussion on Appendicitis.

THE classical sequence of symptoms and physical findings of this disease furnish a standard by which all cases are to be judged. Fortunately most cases conform to type—some vary sufficiently to make diagnosis difficult while a few present baffling phenomena.

The history of sudden acute abdominal pain, usually epigastrie, possibly centered about the navel or rarely in the left abdomen, followed in an hour or two by nausea or vomiting, suggests disturbance in the mid-gut. If some hours later pain is transferred to the lower right quadrant and, upon examination, hyperaesthesia, tenderness or rigidity with peritoncal rebound in this region accompanied by slight rise of temperature, increased pulse rate and moderate leucocytosis are established, the diagnosis of acute appendicitis is justified.

While the symptoms may vary in intensity, the regular sequence of pain, nausea, localization is fundamental in diagnosis and particularly so in differentiating between simple inflammatory and obstructive types. In the former or those associated with infection of the upper air passages, the symptoms may be so nild as to escape observation. Pain may be described as discomfort, nausea absent or transient, tenderness at McBurney's point indefinite, and pulse rate little disturbed, it is true that, with very gentle finger manipulation, mild degrees of muscle spasm can be elicited and accompanying hyperaesthesia. In the obstructive type pain is usually more severe, retching or vomiting is protracted, tenderness, rigidity,

hyperaesthesia marked and pulse rate full and bounding. Doubtful cases should be examined at frequent intervals as obstruction may occur during the course of an apparent simple attack.

There is relative safety when pain is present, sudden termination of pain suggests perforation or the drainage of the appendiceal contents into the cecum. This is followed by subsidence of clinical symptoms which obscures the picture and taxes the diagnostic acumen of the examiner.

One may be permitted to reiterate that study of the pain symptom is most important.

Epigastric pain followed by nausea suggests inflammation or obstruction in the mid-gut, it is colicky in character and not referred, but rather

it is a referred pain.

It must be differentiated from that of biliary colic which is referred to the back and increased by pressure on the ninth costal cartilage; perforated ulcer which is ushered in by sudden severe pain with collapse and rigidity above the navel, rapid pulse and subnormal temperature; acute pancreatitis and mesenteric thrombosis both of which are marked by extreme collapse, exaggeration of pain and vomiting; intestinal obstruction in which, at first, pulse and temperature are rarely disturbed, pain is general, vomiting persistent, abdomen distended not rigid except during spasms of pain and at times bowel picture. It is to be recalled that intestinal obstruction may be caused by the appendix but, as in other cases of obstruction, the cause remains unknown until the abdomen is opened. In general the sequence of

symptoms as they appear aids differential diagnosis. If the patient is seen late with board-like belly wall and peritonitis, the problem is more difficult but that question is not pertinent to my

topic.

In certain cases pain and nausea may be so mild that only when pain shifts to the lower right quadrant does the patient become aware of trouble. He may admit discomfort rather than pain and forget or not have nausea. If a history of previous attacks can be obtained, conclusions may be drawn but it is well to recall that pain beginning at McBurney's point or in the lower right quadrant should be regarded as a reflex until other causes are eliminated.

Alan Lee compares "McBurney's point to a cross-road where intestinal, renal and pelvic systems converge and the site of referred symptoms from numerous distant foci," e.g., sinusitis, tonsillitis, pneumonia, pleurisy, right-sided tubal pregnancy, hemorrhage into ovarian cyst, ovarian cyst with twisted pedicle, Dietl's crisis. Confusion may occur and appendicitis complicate some of these conditions but careful review of symptoms and thorough physical examination will, in most instances, lead to proper dagnosis.

When epigastric or general abdominal pain localizes in the lower right quadrant, superficial hyperaesthesia can be demonstrated in the majority of instances. This is a confirmatory, not

diagnostic symptom.

Tenderness and rigidity are in direct proporton to the location of the appendix, greater if near the abdominal wall, less so if deeply seated,

often absent when located in the pelvis.

Although pain is usually referred to McBurney's point, the point of greatest tenderness is over the location of the appendix, e.g., at costovertebral angle if near the kidney, in the loin if retrocecal or to the right of the rectum in the pelvic variety.

It is well to recall that the appendix is supplied with fibers from the superior mesenteric plexus of the sympathetic and that the reflex may affect the nerves from the 11th and 12th dorsal or the 1st and 2nd lumbar segments of the cord. Usually it follows the 11th dorsal nerve which supplies filaments to the skin near McBurney's point. This reflex may affect motor as well as sensory nerves as seen in local spasm of the abdominal muscles or the psoas with contraction of the leg and pain referred to Scarpa's triangle. The complicated hook-up of those four nerves may produce reflex pain or spasm difficult to unravel.

Why this reflex is ofttimes absent when the appendix is in the pelvis is an unsolved question.

Elevation of temperature usually appears a few hours after the onset of the attack-its presence or absence is not of great importance except in differential diagnosis.

The pulse rate is proportionate, but the volume, quality and rate are most important in estimating

the severity of the infection. Pulse is a friend of the educated finger.

In conjunction with the previously mentioned symptoms, differential leucocyte count is of value as a corroborating factor. In general, the total count indicates degree of resistance, the poly percentage the degree of infection. So many factors may affect the count that it is not to be depended upon as the final word in diagnosis.

Constipation, once considered a symptom associated with appendicitis, must be acquitted because many patients have normal evacuation while some have diarrhoea. In the latter case, enterocolitis must be considered and eliminated.

Hematemesis or hematuria with frequent and painful urination may occur without gastric or renal pathology to complicate the picture. Urinary symptoms simulating renal or ureteral disease occur late in the history of the attack. Strangury is an early symptom in renal or ureteral colic. The latter begins with pain in the lumbar or sometimes epigastric region with nausea or vomitng. Pain travels along right side of abdomen to bladder, testicle or penis. There is frequent and painful micturition and hematura During attacks of pain abdominal muscles become tense but relax during the intervals and, while tenderness can be elicited, there is neither muscle spasm or hyperaesthesia in lower right quadrant.

Repeated urinalysis showing blood, negative blood count, absence of temperature and, in doubtful cases, ureteral catheterization and x-ray of abdomen should make the diagnosis clear. Difficulty is encountered when urinary symptoms are caused by retrocecal appendix attached to renal pelvis or adherent to brim of or located in pelvis.

It is not impossible for both lesions to occur simultaneously. Cases are reported of perioration of appendix into ureter and this complication might prove undiagnosable. Ureteral calculus has been misinterpreted often as appendicitis and is the constant joke of the G-U men but should present no particular difficulty if the case is properly studied.

In the study of each case a careful history of previous illness or attacks and a detailed history of the present attack, noting the order in which the symptoms appeared and their duration, is of primary importance.

Observation of the patient's posture and reaction to pain and respiratory movement are valu-

The physical examination should be general In the approach to the abdomen gentleness in manipulation will be rewarded. Ofttimes slight spasm of the right rectus and oblique muscles can be detected by gentle finger pressure, deep-seated tenderness by firm gradual pressure. In cases of doubt, rectal examination is always in order. Where intestinal obstruction or ureteral calculus is suspected, the flat x-ray plate, properly interpreted, is helpful.

CHRONIC APPENDICITIS?

By GEORGE R CRITCHLOW, MD, BUFFALO, N Y

Read Lefore the Buffalo Surgical Society on Letruary 18, 1932 in a round table discussion on Appendication

PRESUME that the interrogation point punctuating my title is to indicate the skeptieism on the part of someone as to the existence of chronic appendients as a clinical entity I et us define our nomenclature so as to clarify the discussion. The conditions long spoken of as relapsing and recurrent appendicitis are mainfes tations of chronic inflammation having their inception in a primary acute attack. While these conditions are chronic in the sense that they are of indefinite duration they are really a succession of acute attacks with distinct lesions Between such seizures the patient may or may not be free from symptoms. Our present discussion concerns that class of cases with no history of a frank acute attack of appendicitis, but presenting a rather indefinite and variable group of symptoms involving the gastro intestinal tract and tending to focus in the right lower quadrant. Thus our topic is limited to a brief consideration of the question "is the appendix subject to a chronic form of inflammation not a sequella of an acute infection and independent of other intra-abdoini nal pathology?"

It is charged by those who would answer this question in the negative that many appendices are removed that show no pathology and whose possessors experience no relief from the symptoms for which the procedure was undertaken. While this eriticism is doubtless valid regarding a large number of appendectomics, it can be shown, and some of the few case reports later quoted will show, that the converse is true, the pathological findings far exceeding in degree the chincal picture Nor is the absence of demonstrable path ology in the member after removal a proof of failure if there be found unquestioned improvement in the patient's condition post operatively 100% results are rare in the statistics of any surgieal treatment. Some of these failures may be due to madequate preliminary study of the case, resulting in faulty diagnosis. Then again there may be co existing disease elsewhere, not cvi dent at the time but progressing later in spite of the appendectomy Such a situation argues for a proper exploration of the whole abdomen in the absence of acute infection

While the discussions in this symposium are intended to be a reflection of the contributor's personal viewpoint based on first-hand experience, a brief reference to the literature may be allowed A writer in one of our western journals analyzes 100 cases of so called ehronic appendicitis all of which had had a post operative follow up. Thirtyfour gave a history of a previous acute attack, which leaves 66 to be considered as strictly chronic cases according to the terminology postu

lated at the outset of the discussion Ot these 66 all had the symptom of pain in the right side, 50% had nausca and vomiting, 50% had indefi nite indigestion, all had meager abdominal findings on examination, with slight tenderness on deep palpation over the right that fossa. Of these 66 appendices 28 showed no pathology. In the follow-up 427% had the same symptoms as before operation. Many of these patients were opcrated upon with a buttonhole incision, and only a few had preliminary Roentgenological studies This report is quoted to illustrate the point stressed a moment ago, viz, the necessity of eareful examination and differential diagnosis supple mented by thorough exploration on the operating Only by such precrutions will the surgeon best serve his patient and at the same time sparc himself the possible embarrassment of having an other surgion re operate his patient for an illeer or other upper abdominal lesion

Let us try to draw a composite picture of chronic appendientis—one that will not fit every individual case but which will include the essen tial features of the group First, the patient has what Longuet termed "appendicular dyspepsia," a full feeling in the epigastrium coming on with in a half-hour after eating, possibly dependent on the ileo pylorie reflex, the spastic action on the pyloric sphineter eausing retention and acidity. We have all observed at operation the hypertroplied pylorie ring in patients with long standing chronic appendiceal irritation Second, abdominal distress consisting of pain aching or lameness and stiffness in the right lower quadrant, intestinal flatulence, constipution or diarrhoea (if an entero colitis is added to the pathology) Third, sensitiveness to pressure over the lower ab domen, sometimes even to the pressure of clothing, usually elicited by deep pressure over Mc-Burney's, often more marked on pressure with the extended thigh and leg slowly flexed on the abdomen Fourth, toxic symptoms, such as head aches, general malaise anorexia, coated tongue, etc Given a patient with such a chinical picture our first step is to rule out all other likely or possible explanations for the symptoms. If a child we must beware of the ordinary and frequent colics of digestive origin, the occasional painful or sensitive lymph glands of the lower abdomen, and the reflexes from remote conditions in the cliest If a woman it may be difficult to differentrate between a growling appendix and a patho logical tube or overy. In this connection let me remind you of the tremendous help to be gained from a rectal examination. Undoubtedly many an appendix has been condemned for the sins of a ureteral stone on the same side, and many another for the guilt of an ulcerated stomach or duodenum, or a chronically infected biliary tract.

Fortunately we can appeal with great confidence to the radiographer to help us run down the real criminal. Given by the Roentgenologist a negative report on a g.i. series, negative cholecystography, a negative g.u. tract, together with definite and constant visualization of the appendix persisting after the emptying of the cecum and we are not likely to go far wrong in apprehending the miscreant. Larimore of St. Louis contributed to Surgery, Gynecology & Obstetrics, November, 1930. a most convincing article on "Roentgenology of the Appendix." In a reported series of over 4,000 complete gastro-intestinal examinations significant appendiceal findings occurred almost five times as often with visualization as without visualization.

Attention has been called repeatedly to the prevalence of chronic appendicitis in children. Watkins in the Ohio State Journal last June reported a series of 111 cases of appendicitis in children, classified as follows: acute simple, 38; acute suppurative, 19; chronic, 54. We have already noted the great importance of excluding certain conditions peculiar to childhood in making a differential diagnosis. A writer in London Lancet three years ago stressed the fact that chronic appendicitis occurs much more frequently in children than is generally supposed. According to this writer 33% of all cases occur in children.

Mention might be made of a diagnostic sign of chronic appendicitis reported by a writer in one of the French journals, viz., a dilated right pupil. He states that it was observed in 88% of one series and in 93% of another. We have never happened to observe this alleged phenomenon.

McClure of Detroit writing in Annals of Surgery last August discusses the role played by diet and habit in the production of this condition. He calls attention to the fact that while retention of inspissated matter in the appendix is a common finding in this country it is almost never met with in India and Arabia. This he considers to be due to several factors,—food, bowel habits, nerve tension, for example. The natives of these countries eat more roughage, no refined sugar and no canned goods. They are not bound by civilized habits regarding passing of gas, time and place of bowel movements. Another writer calls attention to the fact that in reports of 40,000 Rumanians under medical observation in the rural districts of that country not a single case of appendicitis was seen, while in the cities where more meat and other foods of modern civilization were used the disease was about as common as in European countries generally. Another factor in causation, according to McClure, may be the frequent transient stomach-aches and cramps of adults which may be mild attacks of appendicitis that are undiagnosed. Aschoff and other pathologists agree that recurrence of such attacks causes so-called appendicitis.

Case 1. L.B. F.S. 21. Clerk. Admitted October 5, 1931. Trouble dates back 6 years when she began to have gastric distress with pain and discomfort in the right side. She never had an attack to make her acutely ill, but the symptoms became more constant, she was constinated and had occasional nausea and vomiting. Yesterday taken with rather severe pain in r.l.q. and came to my office in the afternoon. T. 99.6 P. 90 Very sensitive to deep pressure over McBurney point, worse by flexing thigh. No rigidity. Sent to hospital with diagnosis of sub-acute appendicitis. At operation appendix was found long. nodular, non-adherent. Pelvis negative Gall bladder and stomach negative. Laboratory report: size 8 by .5 c.m. congestion of the superficial blood vessels. Wall unusually thin, lumen large, filled with fecal matter. Microscopically the serosa is very slightly thickened and contains a few small congested blood vessels around which was very mild infiltration with lymphocytes. Diagnosis: mild chronic appendicitis. This girl went back to work in two weeks and has lost all her abdominal symptoms of six years' standing.

Case 2. D.B. M.M. 28. Secretary. Father died of appendicitis. Always been in good health. For past two months has had abdominal pain, stabbing at times, usually a dull ache, localized in the r.l.q. Quite sensitive to pressure on deep palpation in that region. Sent to hospital with diagnosis of sub-acute or chronic appendicitis. T.P.R. normal, no blood record, no x-ray. Appendectomy, May 14, 1929. Appendix very long, 5 inches, swollen and injected to gross appearance no adhesions. Pathological report: App. 10 c.m. with very little congestion of superficial vessels; lumen unusually large filled with fecal material; wall correspondingly thin; microscopic section shows nothing of interest. Diagnosis: no pathological lesion.

Schoolmaster. 39. M.S. Case 3. T.T. Office examination, May 5, 1931. Complaint of headache and vertigo for past six weeks or more In the March preceding he had had some pain in abdomen with slight fever, the attack lasting a week, but not keeping him at home. Not seen for 4 months, then re-examined. Headache still present. Abdominal examination elicits tenderness at McBurney point. Seen a month later the tender-Patient is sure he has apness was increased. pendicitis and demands operation. Complete gi series at City Hospital gave negative findings throughout with no visualization of appendix Appendectomy was performed October 3, 1931 Appendix was found kinked, congested in its dis tal third, veil adhesions around the head of cecum Pathologist's report: Marked congestion of superficial blood vessels, walls usual thickness, lumer

small and filled with pus Microscopically, serosa slightly thickened and contains dilated blood vessels around which there is mild infiltration with lymphocytes and pus cells. In mucosa there is moderate infiltration with lymphocytes and pus cells, and a large number of them free in the lumen. Diagnosis acute appendicitis.

In conclusion, to summarize the matter, we be lieve that our own experience furnishes strong evidence of the existence of a clinical syndrome which may be properly termed chronic appendi-While it is a fact that that the pathology is sometimes difficult to demonstrate, yet the results of appendectomy in relief of the symptom-complex in the absence of other treatment justify the diagnosis. On the other hand the pathologist's report will frequently show tissue changes out of proportion to the clinical picture We believe that a preoperative diagnosis of chronic appendicitis should be made only after a most careful exclusion of all other possible conditions, using all the diagnostic facilities at our command. Even when this has been done, it is highly important to check such findings by thorough exploration of the abdominal cavity at time of operation For this reason we believe in an adequate incision

We will not bore you with a lot of monotonous

case reports, but wish to present a few that may illustrate the points discussed. It sho ld be understood that pathologists are not all in agreement as to what constitutes a pathological picture of chronic appendicitis, many of them denying the existence of such an entity at all. There are certain eriteria, however, by which a pathological diagnosis is arrived at by certain groups of pathologists that should be postulated in order to clarify the laboratory reports Briefly, then, an appendix with a histological picture showing injection of the superficial vessels of the serous coat with extravasation of lymphocytes around the vessel walls denotes chronic appendicitis Second, should there be found extravasation of lympho eytes into the walls of the viscus, with or without an occasional polynuclear the report is sub acute Third, swelling and injection of appendicitis the vessels beneath the mucosa with many polynuclears extravasated is the picture of simple acute influmention. Fourth, when these polynuclears are found penetrating from the submucosa into all the walls of the structure, usually with many pus cells in the lumen also, we have a suppurative lesion. The cases now to be cited were all examined by Dr Warwick and classified by the criteria just stated

COMPLICATIONS OF APPENDICITIS. IMMEDIATE AND REMOTE

By M A SULLIVAN, MD, LACKAWANNA, N Y

Read lefore the Buffalo Surgical Society on February 18 1912 in a round table liseussion on Appendicution

AUSCH states, in his opinion, that the appendix is a fiend, and should be abolished at every reasonable opportunity. During la parotomy, right sided hiermotomy, and in those people chronically affected, who anticipate locating in regions lacking surgical facilities, the appendix should be excised as a precaution to a later catastrophy. I am sure all agree that this would prevent many of the complications.

Complications Immediate

Peritonitis—localized Gangrene Rupture Acute gastric dilatation Hemorrhage

Complications Remote

Residual abscess (pelvic, subphrenic, hepatic, subdiaphragmatic)

Embolic abscess (hepatic, pulmonary, cerebral, nephritic, mesenteric)

Pneumonia (lobar or lobular followed by empyema, massive collapse of lung)

Thrombo phlebitis either in portal or general circulation

Involvement of adjacent structures by contact as the adnexae, urmary tract or mac vessels

Intestinal obstruction mechanical or paralytic Acidosis or alkalosis

Lesions of epiploica appendix

Phlegmonous infiltration of the abdominal wall Hernin, abdominal or diaphragmatic

Hemorrhage

Early home treatment is a factor in causing

many of these complications

H A Rayster states that in 1926 seventeen thousand deaths occurred from this disease, twelve thousand of these received cathrities. This fact emphasizes the danger of the old fashioned remedy, namely, castor oil for any intestinal upset and I believe it is a factor in causing rupture with peritonitis, particularly in those cases where the appendix contains a fecal concretion or a foreign body. Murphy states that 38% of his acute appendicitis cases harbored a fecal concretion.

Wilke describes these cases as appendicular ob struction where the outlet becomes obstructed by stricture or kinking, there is putrefaction of the fecal matter distal to the obstruction with disten-

sion causing gangrene and rupture

Pertonulis —True primary pathological conditions of the peritoneum are rare, but there are few if any intraabdominal diseases which at some period during their course do not affect this mem

youngster would have developed a peritonitis and in all probability would have died. This procedure warranted in many doubtful cases will cause no harm to the patient and in many instances be a life-saving measure.

There is difficulty in differentiating between this discase and idiopathic peritonitis and secondly, pneumonia. In so far as pneumonia is concerned it can be eliminated by careful examination including x-rays. In simple pneumonia not clear with the stethescope, x-ray must be relied upon. Where idiopathic peritonitis is concerned if you can make the diagnosis or if not, you have not hurt the child by absolutely determining the type of lesion.

I sometimes wonder whether appendicitis isn't so common that it is overlooked in our efforts to find something more difficult and unusual.

Dr. G. IV. Cottis, Jamestown, N. Y.: I do want to express to you my gratitude for the complimentary invitation to be here tonight. Wright's paper is a masterpicce of conciseness and merit. While the mortality has increased enormously during the last ten years we know that the giving of castor oil and delay has not decreased during that time-the people and the medical man must be better educated. I think the mortality is due to two common causes. First: That the medical profession is not dealing with it as well as they did ten years ago. Second: It seems to me that there are too many men doing surgery today who ought not to be doing it; men who are not eapable of doing it well, and not knowing when they should operate or what they should operate for. I think that many deaths are caused by removing the appendix when the cause was a perforated uleer, etc.

Dr. Critchlow spoke of chronic appendicitis being an inflammatory condition. Without obstruction of the appendix we seldom see chronic appendicitis. In ordinary cases if you watch the pathology, 90 per cent have a fecolith present.

We know it hasn't formed in a few hours of the present attack and that it must have been there a long time, and constitutes in my mind a chronic appendicitis. Most of these patients present gastric symptoms.

I like the way Dr. Lothrop gave the sequalae of symptoms. We all know the sequence of symptoms but don't realize why. The first pain is epigastrie—why. That is the location of all pains coming from the mid-gut. Second, nausea, also a symptom of obstruction of the mid-gut. Then pain and tenderness in the right lower quadrant and by that time inflammation has started up. They become tender because they have a localized peritonitis. You should think of the sequalae of symptoms associated with the sequalae of pathology.

In 1904 Wyeth reported two hundred cases treated without burying the stump of the appendix. It has been shown time and time again if you put in a purse string suture you pass in and out an infected suture and it will eause trouble later on. I hope to see the day when men will

never bury the stump.

Dr. J. M. Mesmer, Buffalo, N. Y.: I know nothing of surgery except the diagnostic points, and it has impressed me tonight that the surgeons are becoming as good diagnosticians as the mediance.

cal men. An appendix can present many, many symptoms and it is with difficulty sometimes that a diagnosis can be made and a decision reached regarding operation.

Dr. Barnes, Buffalo, N. Y.: The question of what, from the x-ray standpoint, constitutes a pathological appendix is frequently raised. The best answer to the question is a definition of the normal appendix.

A normal appendix should fill and empty with, or shortly after, the cecum; it should be movable throughout and should present no greater tender-

ness on palpation than do other portions of the abdomen. Palpation should produce no reflex gastro-intestinal manifestations. Its lumen should be of uniform tapering character. Segmentation and smooth coiling are probably without pathological significance. Kinks, angulations, narrowings, fixations or ovoid filling defects (fecoliths) are abnormal findings.

Dr. H. R. Trick, Buffalo, N. Y.: Before closing the discussion the Chair would like to say that probably each of us has derived definite impressions, but it occurred to me as a result of these papers and discussions that each of us is quite alert to the needs of the occasion, but we haven't explained why the mortality rate is increasing. Some time ago one of the younger men

called my attention to the fact that he had never seen a case of acute appendicitis throughout its entire clinical history and that he had to be at this job for considerable time before he could recognize a case of acute appendicitis. Possibly part of the fault comes back—maybe we haven't been sufficiently thorough in our teaching the undergraduate medical students.

Dr. J. S. Regan, Buffalo, N. Y.: I would like to make a point about the poly and white count. We have seen cases with 8.000 w.b.c. and 84% polys and in cases with 6,000 w.b.c. and 85% polys and the appendix when taken out was covered with fibrin and there was a lot of free fluid in the belly. I saw three cases at the Children's Hospital of acute appendicitis proven at operation and the

white count was only 3,000. I do think the value of the white count lies in its poly count.

Spasm does not need to be present in appendicitis. If the appendix is behind the cecum it will not cause spasm, or if it is in the pelvis it will not cause spasm. I have seen a number of cases missed because the lack of spasm misled the examiner.

Dr. G. R. Critchlow, Buffalo, N. Y.: A good deal has been said about appendicitis in children, but we have on record a case in a man of 85 years of age with acute appendicitis. He had rather a typical picture. He did not want to go to the hospital; he had a blood pressure of 220 and a fibrillating heart. The question was should we kill him or let him die.

Concerning chronic appendicitis—I want to

cite a point brought to my attention by Dr. Warwick, our pathologist. Dr. Irving Potter removes the appendix in every case of Caesarean section he performs. In the course of years he has done hundreds of Caesareans. All these appendices are sent to the laboratory for examination. There has never been an instance in any of these where the signs of chronic appendicitis or appendical irritation has been demonstrable in any degree whatsoever. I think this is very interesting.

Dr. Thew Wright, Buffalo, N. Y.: Don't take it for granted that because Dr. Potter has done a Caesarean section that the appendix is out. It took a great deal of nerve on my part a few weeks ago, when a

patient, who had had two Caesarian sections at his hands, to insist that she had an appendicitis, and at operation I removed a perforated gangrenous appendix that required immediate appendectomy.

Dr. R. R. B. Fitzgerald, Lockport, N. Y.: I want to thank you for the privilege of attending this meeting; I have certainly had my eyes opened. I cannot add, in discussion, anything more than has already been said. In the last ten days I have had two acute cases—one I took to

be influenza. I saw this patient in the morning and in the afternoon had his appendix out and found it to be gangrenous. The other case was one in which the patient had had pneumonia for a couple of days. Under spinal anesthesia we removed a gangrenous appendix.

SCARLET FEVER CONTROL

By FRANK W. L'AIDLAW, M.D., MIDDLETOWN, N. Y.

From the February tenth issue of the Bulletin of the State Health Officers for the District Composed of the Counties of Sullivan, Ulster, Orange, Rockland and Westchester.

The prevalence of Scarlet Fever in a number of places in the district again impels us to devote some space to some commonplace well-known phases of the subject.

Reports of Cases: "No report" is not a good alibi. There are several methods of encouraging failure to report cases.

Doing Too Much: When a family is penalized for being unfortunate enough to have one or two of its members down with scarlet fever, by drastic and unnecessary restrictions, that family and neighboring families will do what can be done to

avoid a repetition of the process. Restrictions imposed upon wage earners engaged in occupations not involving handling of food, 16 by 20 placards, devoting a great deal of attention to the activities of adult members of the household in response to suggestions of officious and vindictive neighbors, encouraging the idea that law, placards, noise and main force directed toward reported cases will control an outbreak, are some of the ways to insure failure to report.

Not Doing Enough: When a physician knows that making a report terminates the incident with the exception of the 20c fee the health officer

charges for reporting the case to the Albany office, can he be criticized real consistently for concluding, "What's the use"?

The First Case: There may be some uncertainty as to just what constitutes an outbreak, but it is obvious that in the beginning the number is mighty small. Devote some time to the FIRST case. After scarlet fever has existed in a community for some time, the "no time," "no help" alibis are good, of course,-the public not realizing that some real work with a definite object done in the beginning probably would have limited the The number of atypical cases as an outbreak continues, becomes a most formidable problem. game.

It is a good idea in the midst of the hullahaloo over closing the school, the location and color of placards, the complaints that quarantined families are "running all over," and that the dog belonging to a family in which scarlet fever exists was scen fraternizing with a neighbor's cat,-to reflect that a few hours work in the heginning might

have prevented the whole affair.

Don't Depend on Alibis: When a case of Scarlet Fever is reported, investigate it. If it isn't reported, investigate it just the same. Cases will be reported if it is known that they will be discovered anyway. Unless you know scarlet fever well enough to make your opinion respected by the other physicians, you shouldn't be a health officer.

See That a Real Investigation is Made: A visit to a communicable disease case is made for three purposes:

To determine the source.

To ascertain to whom the disease may have been communicated by that case.

3. To instruct, and reasonably restrict the family, so that further exposure does not occur.

If you have a nurse who visits cases for the purpose of filling blank spaces on a card, and who cannot be instructed otherwise,-fire her.

If the inquiry indicated that the neighbor's child may also be a case, investigate that case also,-perhaps calling on Dr. - first.

Notify the School: Give the names of the cases and the excluded household contacts, and have it thoroughly understood that these cases and contacts need the Health Officer's certificate to return to school.

School teachers should never fuss about 30- or 7-day exclusion periods; cases and contacts should be excluded until their re-admission is authorized by the Health Officer. Don't try to pass the buck to the school medical inspector,-he has no authority in the matter.

The Education Law: During an outbreak, Sec.

575 of the Education Law should be utilized. A lot of Education people don't know about this section,-and a lot of Health Officers as well. Here it is:

"Whenever upon investigation a pupil in the public schools shows symptoms of any contagious or infectious disease reportable under the public health law, he shall be excluded from the school and sent to his home immediately, in a safe and proper conveyance, and the health officer of the city or town shall be immediately notified of the existence of such disease. The medical inspector shall examine each pupil returning to a school without a certificate from the health officer of the They make good alibis, later in the veity or town, or the family physician, after absence on account of illness or from unknown cause."

Suspects: The first sentence requires the exclusion of suspects. The health officer is to be notified of such exclusions. It is obvious that such pupils should return to school with the O.K. of the health officer. A number of opinions are prevalent as to the impracticability of this provision. none of which are any good. Of course the health officer may need an assistant if the check-up is not started until practically every pupil in the school is involved.

Absentees: The second sentence is an important one,-so important that we repeat it:

"The medical inspector shall examine each pupil returning to school without a certificate from the health officer of the city or town, or the family physician, after absence on account of illness or from unknown cause."

If the pupil returning without a certificate from the Health Officer is one included in the list of cases and household contacts furnished the school by the health officer, he leaves promptly, and stays out until he has the health officer's certificate.

If the pupil is one the school authorities have excluded under the first part of the section as a suspect and of which the health officer has been notified, the procedure is the same,-the pupil goes home, and comes back when he has the Health Officers' certificate.

The child who has been home sick from a nonreportable condition, comes back to school with a physician's certificate. If he has no certificate, the school medical inspector examines him. If the school medical inspector has reason to believe that the pupil may have been sick with scarlet fever or any reportable disease, it is very obvious that he should refer the case to the health officer.

Of course there are many reasons advanced to demonstrate the impracticability of the foregoing, none of which are sound, and all of which relate to the period after the outbreak has gotten out of hand.

LICHENOID SARCOID (BOECK)

Report of a Case with Review of the Literature By JOSEPH L. MORSE, M.D., NEW YORK, N. Y.

From the Department of Dermatology and Syphilology, N. Y. Post-Graduate Medical School and Hospital, Dr. George M. MacKee, Director. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

CINCE Boeck's notable paper in 1899, the sarcoid group has been of great interest to dermatologists. He originally recognized and described three types of this group, the large nodular, the small nodulo-papular, and the diffuse infiltrating form. In his original description, Boeck mentioned groups of numerous, very small, bluish or brownish-red papules on the left thigh of his patient. They resembled lichen planus to, It is remarkable that, altho Boeck's first case had these "lichenoid" lesions, so comparatively few other cases of this type have been reported since. However, I am of the opinion that this form of sarcoid may not be as rare as the number of reported cases would lead one to believe; and it is highly probable there are more cases than I have been able to discover which have been reported as lichen planus or otherwise that were in reality this lichenoid form of Boeck's

Hallopeau and Eck² in 1902 reported a case of Boeck's sarcoid. They did not describe lichenoid lesions, but later in a report³ on the progress of the patient under treatment with Fowler's solution, tell of the improvement and modification of the original eruption with the appearance of many lichenoid lesions resembling lichen planus. Unfortunately they did not do a biopsy on these new lesions and the question is whether they were lichen planus papules following arsenic medication or the lichenoid form of sarcoid. This case must therefore remain doubtful.

Winkler⁴ in 1905 wrote a rather extensive paper on Boeck's sarcoid, with a report of a case proven microscopically. In his description of the eruption, he stated that there were also present superficial papular lesions, arranged in groups and lichenoid in appearance.

Zeisler⁵ in 1915 reported a case of generalized multiple benign sarcoid in which he described lichenoid papules on the legs and several flat

lichenoid lesions on the glans penis.

Kuznitzky and Bittorf's⁰ case, the same year, was one of Boeck's sarcoid with involvement of the internal organs, proven at autopsy. There were, besides the typical sarcoid lesions, numerous disseminated papules, brownish in color with bluish and yellowish centers. These looked, for the most part, like lichen planus, but also simulated a papular syphiloderm.

In 1919, Bruusgaard⁷ reported five cases of Boeck's sarcoid. The fourth case of the series was one in which there were typical nodular lesions on the face along with a group of lesions of

the lichenoid form on the right leg.

Fox⁸ presented a case with a questionable diagnosis of lichen planus at the dermatological section of the New York Academy of Medicine in 1921. There were lichenoid lesions on the nape of the neck, along with lesions on the face and backs of the hands. It happened that Dr. D. L. Satenstein, dermato-pathologist at our clinic, had a slide of that case which showed nothing suggestive of lichen planus. There were, however, in the mid and upper cutis isolated tubercles with a moderate inflammatory reaction about them. The tubercles were composed of epithelioid and giant cells. These histological findings fit in with that of a superficial sarcoid and I am therefore including this as a case of lichenoid sarcoid.

Rischin's case, in 1922, presented a universal eruption which he at first thought was lichen ruber. This case also had involvement of the internal organs. The diagnosis of sarcoid was

made histologically.

In 1925, Wright¹⁰ published his unusual case under the title of Lichenoid Sarcoid. This case is unique in the literature, in that it appeared first as areas of depigmentation in which lichenoid papules later developed. There were no other sarcoid lesions. A biopsy revealed the diagnosis of sarcoid.

Kissmeyer, in 1930, wrote an excellent article on the lichenoid form of sarcoid. It was of great help to me in writing this paper and I hereby wish to acknowledge my thanks. He reported two cases of lichenoid sarcoid both of which were proven histologically. The first one consisted entirely of a large group of yellowish lichenoid papules on the sternum. As in Wright's case, there were no typical lesions of sarcoid. In the second case, there were infiltrations on the nose and cheeks, typical of Boeck's sarcoid, with a group of lichenoid papules, resembling lichen planus on the right knee. This case closely resembled Bruusgaard's. It is also of interest to note that this second case, on x-ray examination of the phalanges of the fingers and big toes, revealed the cystic bone changes which are thought to be pathognomonic of sarcoid.

Report of Case*

History.—Mrs. J. S., age 53, widow, born in Italy, was referred to Dr. George M. MacKee. She had an eruption of two years duration. It had first appeared as "red spots" on the arms and similar lesions continued to develop on the fore-

^{*}This case was presented October 23, 1928, by Dr. George M. MacKee at the New York Derm. Society; Arch. Derm. and Syph. 19, 515, 1929.

head, nose, cheeks and ears. About a year after onset, many smaller lesions appeared on the back of the neck. These were quite different from the others. There were no subjective symptoms and

Figure 1
Nodular lesion on nose and annular lesions on cheek;
also shows infiltrated lesion on forcheod.

patient felt well generally. Some of the lesions on the arms had been treated with an acid, otherwise she had had no treatment and the lesions had not changed in appearance. There was nothing significant in the past or family history.

Examination.—The patient was very well nourished and seemed to be in good health. Physical examination was negative except for the following. There was some diffuse enlargement of the right lobe of the thyroid which was freely movable. The lungs showed dullness in the left apex posteriorly and broncho-vesicular breaching in the left infraclavicular region. There were no râles. She had some tenderness in the gall-bladder region and the liver was felt two fingers below the costal margin. There was no adenopathy. The reflexes were normal.

The eruption occupied the forehead, nose, cheeks, ears, back of neck and extensor surfaces of both forearms. In each of these locations the eruption presented an entirely different appearance. On the forehead there were several violaceous plaques, varying in size from a dime to a quarter, infiltrated, smooth, and slightly elevated. The lesion on the nose was a violaceous, oval, quarter-sized tumor, more elevated than those on the forehead. The eruption on the ears consisted

of several small, scaly, violaceous lesions, slightly infiltrated, with some atrophy, suggestive of lupus erythematosus. On the cheeks and extensor surface of each forcarm were many violaceous, oval and round, dime-sized, flat, slightly infiltrated lesions. The centers of most of these were slightly atrophic and had less color. The

FIGURE 2

Annular lesions on forearms.

appearance of the lesions on the forearms was probably partly, if not entirely, due to several acid applications patient had previously received. The margins of these lesions were very slightly elevated and consisted of tiny, flat-topped, shiny papules, giving the appearance of annular lichen planus.

On the back of the neck there were a large number of closely crowded papules, ranging in

Figure 3
Lichenoid lesions on back of neck.

size from a pinhead to a small pea. They were flesh colored, that is they were about the color of the normal skin of the patient, who was a decided brunette. On diascopic pressure they were yellowish in color. The lesions were flat-topped, shiny and some of them were umbilicated. Where

lesions were very close together there was a suggestion of a mosaic or lichenification. With the exception of the color and the hard consistency, the eruption on the whole looked like lichen planus. The only lesions typical of sarcoid were those on the forehead and nose. There were no lesions in the mouth.

Laboratory Examination.—Wassermann and Kahn tests were negative. An ordinary specimen of urine was negative except for a very slight trace of albumin. The red, white and differential blood counts were normal. Graded tuberculin tests were negative in dilutions of 1:1,000,000, 1:100,000, 1:10,000 and 1:5,000; 1:500 and 1:100 both gave +++ reactions. A small piece of tissue from one of the lesions was excised, under sterile precautions, ground up and suspended in salt solution and injected subcutaneously into a At the end of six weeks, the pig showed no enlarged glands or loss of weight and three months later was living and perfectly well. Several examinations of the tissue excised were negative for tubercle bacilli.

Dr. William H. Meyer, Director of the Department of Roentgenology of the New York Post-Graduate Medical School and Hospital, reported on the x-ray examination of the chest and bones of the hands as follows: "The lungs showed advanced second stage tubercle infiltra-

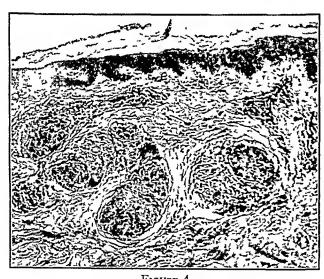

Figure 4

Low power of lichenoid lesion from back of neck.

tion of both upper lobes, in transition to third stage or fibro-bronchiectasia at the apices. There was no gross abnormality in the position, detail or outline of the bones of the hands, except prominences at the bony ridges and tendon insertions, changes frequently noticeable with advancing years."

Histologic Examination—Biopsies were taken from lesions on the back of the neck and right forearm. Dr. David L. Satenstein reported:

"Lesion from the neck: Low power examination revealed in the upper cutis, to one side of a follicle, a number (4) of fairly sharply defined cell accumulations without any relation to the vessels. To one side and above these cell groups are somewhat dilated small vessels with a cell accumulation in the perivascular lymph space. In the remaining portions of the upper cutis the vessels are dilated with some cells about them,

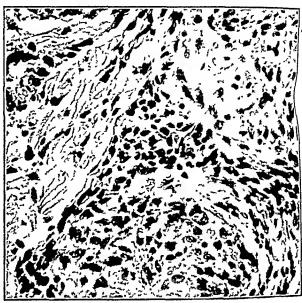

FIGURE 5
High power of tubereles (lesion from the neck).

Throughout the entire cutis there is a definite interstitial edema. The epidermis is apparently unchanged except that portion overlying the cell accumulations which is somewhat flattened out. There are no cell accumulations either about the follicle, sebaceous gland, coil gland or its duct The deeper vessels are not involved.

High power showed the cutis framework (collagen bundles) twisted aside by the cell accumulations to form a suggestion of a capsule. There are no fibres or bundles of connective tissue between the cells. These accumulations are polymorphous in character. The predominant cell is the so-called epithelioid cell, which in this specimen is fairly large. The cell-body is in part margined, in part indistinct; variously shaped, from polyhedral to elongated spindle in outline. In places it is somewhat homogeneous, but in greater part is finely granular. Some of these large polyhedral cells possess dendritic processes which appear to join on to neighboring cells The majority of these cells contain one nucleus, a few larger ones contain numerous nuclei (giant cells). The nuclei are of the so-called vesicular type (fairly sharply margined, with a loose chrematin network and visible nodes). Between these so-called epithelioid cells are densely stained roundish nuclei with hardly any noticeable rim of cell body. In the collagen, outlying the cell groups, are elongated connective tissue cells with elongated nuclei. The vessel walls are swollen, the endothelial lining projecting into the lumen. The cells in the perivascular lymph spaces are mostly of the small lymphocytic type. There are no plasma cells visible anywhere. There is no evidence anywhere, either in the cell accumulations or in the cutis framework, of any type of degeneration or necrosis.

Résumé: The cell accumulations (tubercles) are similar to those noted in various types of tuberculosis but differ markedly from those noted in tissue other than the skin. The inflanmatory reaction present is of a mild type and is apparent-

ly not in relation to the tubercles.

Lesion from the arm: Low power examination showed in the upper cutis, reaching up to and apparently pressing on the epidermis, both discreet and confluent accumulations of cells which is suggestive of a broad band infiltration directly under the epidermis. The connective tissue bundles are pressed aside with slight tendency to form distinct capsules. To one side and apart from the cell accumulations are somewhat dilated vessels and cellular infiltrations about them. To one edge of the section and entirely separated from the previously mentioned cell groups are a few isolated discrect similar cell groups. vessels in their neighborhood are also somewhat dilated; there is a moderate cellular infiltration about them. There is an interstitial edema throughout the cutis. The epidermis is unchanged except over the cell accumulations where it is flattened out and definitely thinned.

Under high power it is seen that the discreet cell accumulation (tubercle) is composed predominantly of very large, irregular and multi-nucleated cells (giant cells). The cell bodies are distinct in outline, have many fine projections and are in part finely and in part coarsely granular. The nuclei are of the vesicular type. Some of the lymphocytic type are also present (probably inelusions). There is a considerable degree of vacuolization. About the giant cells are numerous so-called epithelioid cells of varying sizes and shapes. Scattered among them are some lymphocytes. Plasma cells are not present. There are no blood vessels in this zone. In the zone where the cell groups are fused together as a band, one can note the definite limitation of the tubercles. The cells are predominantly of the epithelioid type, few of the multi-nucleated cells being pres-

ent. The outline of most of the cells is rather indistinct. In this zone there are no plasma cells. There are no connective tissue fibres or bundles between the cells. There is no evidence of degeneration or necrosis in any part of the tissue. The epidermis overlying the so-called tubercles is flattened out to a thin plate, composed of a few parallel rows of cells.

Résumé: In the lower portion of the upper eutis are isolated tubercles (in all probabilities the last to develop), whereas in the sub-epidermic zone the tubercles show a tendency to run together, encroaching on the epidermis. In this specimen the inflammatory reaction is in the surrounding cutis and not in relation to the tubercles.

Conclusion: From the character of the component elements of the tubercles, we may assume the slow but fairly progressive development of the clinical lesions. There apparently is little evidence of any local tissue reaction (from the lack of inflammatory or degenerative manifestations), nor is there evidence of development of a local immunity (absence of plasma cells). The histologic evidence is that of tuberculous type tubercles with little inflammatory reaction. Diagnosis-superficial sarcoid (Boeck).

Treatment: Patient first received four exposures of one-fourth of an erythema dose of unfiltered x-rays, given at weekly intervals, without any improvement in the lesions. She was then put on gold sodium thiosulphate intravenously, injections given once a week. We were using larger doses of gold then and began with a dose of 50 mg. gradually increasing to 100 mg. She showed improvement after the eighth injection and the eruption was entirely gone two weeks after the twenty-sixth injection. There has been no recurrence since.

SUMMARY

1. A review of the literature revealed ten cases of Boeck's sarcoid with lichenoid lesions. In only two cases, Wright's and Kissmeyer's, were there lichenoid lesions alone without other lesions typical of sarcoid.

2. This rare form of sarcoid should be kept in mind in atypical lichenoid eruptions. Biopsy and careful histologic study are of paramount importance in these cases.

3. Another case of Boeck's sarcoid with lichenoid lesions is reported.

4. Gold sodium thiosulphate intravenously cleared up the eruption.

Discussion: Dr. Louis Tulipan, New York, N. Y. There is no question of the case presented by Dr. Morse, being one of Lichenoid Sarcoid. The only objection I have, is the fact that we are cluttering up our literature with unnecessary names. Boeck himself in his first publication in 1899 mentioned an eruption consisting of groups of small pinhead sized papules in some places grouped, resembling Lichen planus, Hallopeau and Eck (1903) presented a similar case, while MacKee in (1929) showed one in New York.

Of course this type of sarcoid is uncommon and has been thoroughly worked up by the presenter in the case reported today.

A SUMMARY OF THE PHYSIOLOGY OF THE FEMALE REPRODUCTIVE SYSTEM

Some Clinical Observations*

By NATHAN P. SEARS, M.D., SYRACUSE, N. Y.

THE history of our present understanding of the physiology of menstruation dates from 1896 when Knauer discovered that the ovary was a gland of internal secretion and that it controls menstruation by such a secretion. To enumerate all the events that have taken place since then would be far beyond the scope of this paper. It is my purpose only to bring before you in a brief manner the facts as they appear today.

Soon after Knauer's work appeared, Hitschman and Adler demonstrated the changes which take place in the endometrium during the menstrual As soon as these fundamental processes were established, attention was directed to the histology of the ovary, the origin of the lutein cells and the correlation between the follicle cycle and that of the endometrium. During this period the corpus luteum held the stage of investigation and by many it was considered to be the essential structure of the ovary. This opinion seemed logical since its structure so closely resembled that of some of the already familiar ductless glands. Frank's discovery in the Graafian follicle of a hormone which produced changes in uterine contraction similar to those seen at normal oestrus brought attention to this substance. After it had been discovered by Stochard and Papanicolaou and Allen and Doisey that the vaginal epithelium of certain rodents hypertrophied during oestrus, this phenomenon was used as a test to determine the presence of follicular hormone. Frank then found this substance not only in the follicle but also in the corpus luteum and placenta, and applied to it the term female sex hormone.

The finding of female sex hormone in the corpus luteum was rather confusing since Leob, Novak and others still believed that this body had a separate hormone. This question was solved in 1929 by Corner who found in the corpus luteum another secretion, progestin, which he proved

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffelo, N. Y.; May 24, 1932.

stimulated the premenstrual hyperplasia of the endometrium.

The following sequence of events can, for the present, be considered as facts, although it may be possible that some of them are open to question and future investigation may necessitate a change of opinion.

The pelvic structures most important in the physiology of menstruation are the graafian follicle (including the corpus luteum stage) and the The life history of the graafian endometrium. follicle begins with the primordial follicle, a small vesicle, containing the primordial ovum and lined with small spindle cells. As development proceeds, the lining cells lose their connective tissue character, become pale, cuboidal granulosa cells and are arranged in a multi-layered membrane, the membrana granulosa, lining the cavity of the Extending into the follicular graafian follicle. fluid, as a peninsula, is a group of cells, the discus proligerous, which surround the ovum. As the graafian follicle ripens, it enlarges and finally 15 forced to the surface of the ovary where it rup-From histological tures liberating the ovum. study it has been estimated that rupture takes place on or near the fifteenth day of the cycle. Recently Pratt and Allen have obtained ova from tubal washings and their appearance seems to indicate that they were released between the fourteenth and sixteenth day.

Just before the rupture of the follicle, the proliferative stage of the corpus luteum begins, the granulosa cells increase in size and show signs of activity. Mitosis may be seen and the granulosa layer is separated slightly from the theca interna. After rupture of the follicle the proliferative stage continues, the cells taking on a faint yellow color and becoming the lutein cells. This origin of lutein cells is generally accepted, but some believe that the theca interna which immediately surrounds the membrana granulosa also plays a part. Grossly the freshly ruptured follicle (corpus

luteum) is a thin walled, collapsed vesicle lined with a thin pale yellow layer of lutein cells.

The second stage of corpus luteum development, the vascular stage, is characterized by the extravasation of blood into the yellow substance and the appearance of capillaries between the columns of cells. The lutein layer becomes thicker and the cells more yellow. When fully vascularized the corpus luteum has reached the stage of maturity. It now presents a deep wavy yellow wall and the V-shaped columns of para-lutein cells dip into its substance from above. If the expelled ovum has been fertilized, the corpus luteum continues to develop as the corpus luteum of pregnancy. If it is a part of an infertile cycle it soon regresses, is replaced by connective tissue and in a few weeks becomes a pale fibrous body, the corpus albicans.

Concurrently with the life history of the follicle, the endometrium is undergoing changes. There are three layers of the uterine mucosa, from the lumen to the muscularis they are as follows: the compacta, a shallow layer made up principally of stroma and containing a few narrow glands; the spongiosa, a soft layer, rich in glands, which undergoes the greatest changes during the cycle; and the basalis, a compact glandular layer next to the muscle.

The normal menstrual cycle requires twentyeight days. For convenience, the first day of the bleeding period is accepted as the first day of the cycle. As the corpus luteum of the last cycle regresses, desquamation of the upper two layers of the uterine muscosa occurs, leaving the basalis ' from which regeneration takes place. Desquamation requires three days but bleeding normally lasts five. By the fifth or sixth day of the cycle regeneration has taken place and there are again the three layers of endometrium but in miniature form. At this time a new follicle is developing in the ovary and under its stimulation the endometrium develops. During the stages of proliferation and vascularization of the corpus luteum, the endometrium is gradually changing. glands, especially of the spongy layer, increase in length and width and begin to show some tortuosity. When the corpus luteum has reached the stage of maturity the endometrium shows the active secretory or pre-menstrual condition. This phase is characterized by great activity of the glands. They are long and tortuous with papillary buds of epithelium extending into their lumina so that they present on section a wavy, feathered appearance. Thus the uterine mucosa is prepared for the reception of the fertilized ovum. If fertilization has not taken place, regression begins and a new cycle is in progress. (The relation of the follicle and the endometrium in the infertile and fertile cycles is seen in the first two groups of Fig. 1.)

What initiates this complex process of coordi-

nation between the action of the ovary and the changes in the uterine mucosa? Fröhlich, Cushing and others have noted the effect on genital function of disease and of removal of the anterior pituitary body. Some fifteen years ago, by feeding anterior lobe to immature rats, Emil Goetsch produced in them marked changes in growth and sexual development. Recently, Long and Evans, and Zondek and Aschheim, by injection and transplantation experiments, respectively, showed that the anterior pituitary is vitally important to ovarian function. As a result of their work it is now believed that there are two hormones in the anterior pituitary that affect the action of the ovary; Prolan A, stimulating follicular development and ovulation, and Prolan B, stimulating the luteinization of the follicle.

To summarize the physiology of menstruation, we can say that there are three structures necessary. In the chronology of their activity they are as follows: first, the anterior pituitary producing its secretions, Prolan A and B; second, the ovary, producing the secretions of the follicle and the corpus luteum; and third, the endometrium, upon which these actions finally take place. This activity can be visualized in Figure 2. Prolan A acts on the follicle which in turn stimulates the early development of the endometrium; Prolan B stimulates the formation of corpus luteum which in turn produces the premenstrual hyperplasia.

During the study of the physiology of menstruation, the tests used on the animal to determine the function of the ovary and pituitary body were applied clinically. It was found that in normal women female sex hormone appeared in the blood for five or six days before the onset of menstruation and that it could be obtained from the urine at certain phases of the menstrual cycle. It was also noted that in pregnancy there were large amounts of the luteinizing hormone of the anterior pituitary substance in the urine. These reactions then became of clinical importance. can now, by injecting treated blood or urine into the spayed mouse, be determined whether or not the individual has the normal amount of female sex hormone in the blood and if it is properly excretcd in the urine. These findings are helpful in determining the basis of dysfunctional bleeding and giving a prognosis in prolonged amenorrhea. The fact that the luteinizing substance of the anterior pituitary is greatly increased in the urine during pregnancy makes this a valuable test for this condition. Other uses for these procedures have been mentioned but are not as yet sufficiently standardized to be generally relied upon.

It is not strange that errors of function may occur in one or more of the phases of the complex mechanism of menstruation. It is now supposed that certain types of functional bleeding are due to such a lapse of function. This condition may occur any time between puberty and the menopause. The bleeding in these cases is almost constant, each period lasting with a bloody discharge for many days, even continuing into the next

cycle.

The present explanation of this bleeding; namely, the absence of corpus luteum formation, is based on the appearance of the endometrium and of the ovaries. The former shows an exaggerated mid-period reaction with none of the premenstrual characteristics produced by the action of the corpus luteum. The ovaries contain no corpora lutea but many graafian follicles in an equal stage of development. Within the limitation of our present knowledge, we may, therefore, assume that this type of bleeding is due to the absence of corpus luteum and the excessive production of follicular secretion. Fig. 1 demonstrates diagrammatically the present conception of the physiology of function bleeding (Sub. Fig. 3), as compared with the normal physiology (Sub. Fig. 1).

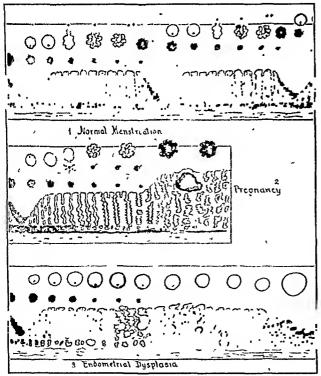

FIGURE 1.
Physiology of reproduction.

The first duty to women suffering from this malady is to rule out, with certainty, any pathological condition. Their study, besides a complete physical examination, should include a basal metabolism determination, a curettage and complete blood studies including blood calcium. If facilities for determining the female sex hormone in the blood and urine are available, this should be done. The diagnosis after finding no pathological condition capable of producing uterine bleeding, rests on the characteristic hyperplasia of the mid-

period endometrium with its "Swiss cheese" pattern, and an excessive amount of female sex hormone in the blood.

Treatment of this condition has been difficult. If the above theory be right, it would be possible to correct the faulty action by the use of progestin. Since this substance is not available for clinical use, another plan must be devised. Novak has reported a group of cases in which he successfully used the luteinizing hormone of the anterior pituitary (Prolan B). Theoretically this substance should produce luteinization of the follicle and thus complete the cycle. However, Samuel Geist in discussing Novak's paper stated that he had had the opportunity of observing the ovaries of women who had received large doses of luteinizing substance and has failed to see any histological change in them. He stopped the bleeding, however, in six of fourteen cases to whom he administered this substance.

In studying thirty-one cases of functional bleeding, I found twenty to have basal metabolism readings of from minus 10% to minus 30%. There were eleven with normal basal readings. Of the former, seventeen remained well while taking thyroid extract. One was unrelieved, refused complete study and would not return when luteinizing substance was available. The other two received thyroid and luteinizing substance. One had bled almost constantly for eleven years. After one course of luteinizing substance and taking three grains of thyroid a day, she had eight normal periods. The ninth was prolonged and profuse but she is now normal again after another course of luteinizing substance." The last of this group had thyroid for a time, it was then discontinued and luteinizing substance was given with very little improvement. Lately she is receiving both and is very much improved.** The eleven patients with normal metabolism stopped bleeding promptly when given luteinizing substance.

Another group of patients falling under the heading of deranged function are those having long periods of amenorrhea. Their inter-menstrual intervals vary from three to eighteen or twenty months. Their condition is evidently due to failure of follicular function. Many of the mild cases can be helped by the oral use of anterior pituitary and thyroid, but the more persistent ones need more potent treatment. The use of the newer ovarian products is helpful but at best it is a substitution therapy. It seems more rational to stimulate, if possible, the patient's ovaries. The following case report exemplifies Miss A. I., age 21, was first seen this idea. Jan. 19, 1931. Her menses began at 13 and

^{*} Because of only partial relief and extreme worry about her condition this patient has recently had a partial hysterectomy in another city.

^{**} Since this paper was read, it has been necessary to use x ray in an attempt to regulate this patient's bleeding.

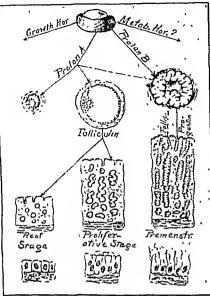

FIGURE 2.
Physiology of reproduction.

were always scant and irregular, appearing at three to five month intervals. Her last period was in July, 1930. Six months before she consulted me, her basal metabolism was minus 40%. The rate was minus 10% when I saw her, Physical examination was negative, body contour, primary and secondary sex characteristics were normal. Anterior pituitary grs. 15 q d was added to the thyroid grs. 11/2 which she had been taking She flowed one day in March, 1931. Later she received 1000 units of theelin with no effect. On Dec 12, 1931 I saw her again. She had had no period since March. From Dec. 12th to 30th she received 120 R.U. of anterior pituitary. On Dec 30th she began a four-day period. On Jan. 15th and Jan. 16th, 1932, she received 50 R.U. each There was a one-day period on Feb 3rd: March 10th and April 13th each started a five-day period Her general condition and mental attitude are excellent, she was recently married and is quite normal and happy.

SHMMARY AND CONCLUSIONS

(1) Menstruation depends on a coordinate relation between the anterior lobe of the pituitary, secreting Prolan A and B, the ovary with its follicular and corpus luteum hormones, and the endometrium.

(2) Derangements of this mechanism result in

functional disorders of menstruction.

(3) We are beginning to understand this intricate process, our goal is not yet reached, but if we go on carefully and judiciously we can in time solve this question and by its solution correct in a retional manner many conditions now treated by radical and empirical methods

Description of the Figures

Figure 1. (After Schroeder, recopied from Graves' Hormonology) consists of three parts. In each is seen a diagram of the endometrium under different conditions. Above the endometrium is represented the stages of follicular development corresponding with the different phases of the endometrial cycle.

In the upper group are represented two complete menstrual cycles. The complete group of follhele figures belongs to the first endometrial cycle and represents the enlargement of the follicle, its rupture at about the mid-menstrual period, the corpus luteum coincident with the premenstrual hyperplasia and the regression of the corpus luteum corresponding, and the desquamation phase of the endometrium. The small black spots inducate the continued regression of the corpus luteum.

In the middle group is shown a fertile cycle The follicle rupture, fertilization of the ovum, the true corpus luteum and the embedding of the embryo unto the prepared endometrium.

In the lower group is seen the supposed behavior of the follicle and endometrium resulting in dysfunctional bleeding. There is no follicular rupture and no corpus luteum. The endometrium shows a persistent exaggerated mid-period reaction; and no secretory or premenstrual phase is seen.

Figure 2. (After Zondek, recopied from Graves) Here is represented the relation between the anterior pituitary, the follicle, corpus luteum, and the different phases of endometrial function. The broken lines indicate that the corpus luteum also contains besides progestin, follicular secretion.

STRUCTURAL CHANGES OF THE AORTA DUE TO ARTERIOSCLEROSIS, AS OBSERVED ROENTGENOLOGICALLY

By WALTER W. FRAY, M.D., and JOSEPH H. GREEN, M.D., ROCHESTER, N. Y.

From the Division of Radiology, Department of Medicine of the University of Rochester School of Medicine and Dentistry, and Strong Memorial Hospital, Rochester, N. Y. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

A RTERIOSCLEROSIS produces definite morphologic changes within the aorta which can be identified roentgenologically. It is the purpose of the present paper to describe these changes, illustrating each with typical roentgenograms of subjects who have been autopsied. The gross and microscopic appearance of the pathological lesions of these aortae have been studied in detail.

Arteriosclerosis of the aorta characteristically begins in the intima as slightly raised plaques, representing a thickening of the intimal layer due to a proliferative growth of the connective tissue of this layer, with subsequent fatty degeneration, hyalinization, and often necrosis. As a result of these later changes, the plaques may become considerably elevated, soften, and eventually slough, leaving a frank ulceration of variable shape and size. During the more advanced stages, the elastic tissue elements disappear and calcification of the scarred areas may ensue. The media, if involved at all, shows changes mainly of the degenerative type, with fatty degeneration, calcification, and destruction of the muscular tissue elements. Bands of dense fibrous tissue may penetrate even the deeper portion of the muscularis, replacing the destroyed elements of muscular and elastic cells.

A consideration of these changes is important because they lead to a progressive loss of elasticity and contractility of this vessel. The aorta may dilate, producing some increase in its transverse diameter, but more commonly elongation, the result of longitudinal stretching, is the main effect observed.

The changes resulting from this elongation can be determined with considerable accuracy by roentgenological means. Some of the features of this elongation have been emphasized by such writers as Dann (1930), Sproull (1931), Rösler (1931). Recently, Fray (1932) has shown that the altered spatial relationships of the aorta within the thoracic cavity can be demonstrated by comparative measurements of the aortic arch and the chest cage. The manner in which this can be done will be illustrated in the present study by specific cases which have recently been studied at autopsy.

Method of Examination

A complete roentgenological examination should consist of fluoroscopy and at least two roentgenographic films of the heart and aorta. The fluoroscopy is of particular value in giving information concerning the dynamics of the aorta, its size, degree and type of pulsations, abnormal expan-

sions, etc. It enables the examiner to turn the patient at various angles, thereby permitting a general orientation of the arch within the chest cage, and to select the most favorable position for the left oblique film. The arteriosclerotic aorta is quite frequently particularly well seen during the fluoroscopy because of its greater density. Often calcium plaques within the wall of this vessel are clearly visible when seen in profile as at the aortic knob.

The posteroanterior film is obtained in the usual manner, with the anterior aspect of the chest against the plate changer employing at least a 6-ft. distance between the target of the X-ray tube and the film. The patient is instructed to take a moderate inspiration without straining. For the purpose of examination of the aorta only, the exposure time is not important, provided the other factors have been properly selected.

The left oblique film is of even greater importance in a study of the aorta. By turning the patient so that the left anterior aspect of the chest is in contact with the plate changer, the two limbs of the aortic arch are separated and are brought into full salience. The degree of turn necessary varies in different individuals, but is commonly close to 45°. The exact amount of turning is best determined by carrying out the fluoroscopy Under fluoroscopic control the patient can be turned gradually until the two limbs of the arch show maximum separation. The attempt is then made to duplicate this same position for the film exposure. Greater accuracy can be achieved if this angle is measured at the time of the fluoroscopy; exact duplication is then possible for the film technique.

This film is secured at the end of a moderate inspiration. To avoid the superimposed shadows of the arms, the left arm is placed behind the body, while the right arm is elevated by placing the hand on the upper edge of the plate changer. The kilovoltage, and often the time, must be considerably increased in order to obtain a film with good detail at this angle. In a limited number of cases it will be found advisable to secure a right anterior oblique film. This film, as a rule, is not of great importance, although at one time it was used extensively in a futile attempt to determine the calibre of the ascending aorta.

The posteroanterior and left anterior oblique films usually give all the information necessary. The complete analysis of these films requires both direct inspection of the films and mensuration—particularly of the left anterior oblique film. The usual inspection of the film commonly gives information concerning two outstanding charac-

teristics of arteriosclerosis: (a) the presence of calcium plaques, and (b) tortuosity.

The former is usually identified on the posteroanterior film at the aortic knob. Calcified plaques may be caught "on edge" in this location, which can be readily recognized on the posteroanterior film, but often a Bucky technique is required to outline them clearly. Positive identification of these plaques gives indisputable evidence of arteriosclerosis (Lantern slide). This is a local film of the aortic knob region, taken with a Bucky technique. The patient was an elderly woman who subsequently died at the hospital, and the presence of calcium in this region was verified at autopsy.

Tortuosity is the direct result of diffuse aortic elongation. It may produce an unusual prominence of either the ascending or descending aorta on the posteroanterior film, resulting in an increase in the measurement of the great vessels. An abrupt turn in the descending limb of the aortic arch results in an accentuated aortic knuckle. The descending aorta may swing far out of its normal course and be seen behind the heart in the posteroanterior film far to the left of its usual course, or may swing medially to cross the midline, in which case the outline of the descending aorta may be actually observed on the right side of the body. The actual course of the aorta is often more easily followed in the left anterior oblique film, comparing the appearance with that observed in the postcroanterior film.

The following case demonstrates the marked tortuosity which may occur. J. C., age 93, was admitted to the hospital complaining of pain in his left leg and foot. The cardiac rhythm was regular except for frequent extra-systoles. The peripheral arteries were thickened, beaded, and tortuous. The dorsalis pedis and posterior tibial pulsations could not be felt.

The posteroanterior film of the cliest shows a marked prominence of the ascending aorta and aortic knob.* There is a sharp bending of the upper descending aorta in the posteroanterior film. In the oblique film the aorta is markedly tortuous, taking an "S" shaped bend in its descending portion.

It is interesting to note that, although the posterior tibial arteries and portions of the dorsalis pedis arteries showed a marked degree of calcification, no calcification is seen in the aorta with the usual chest technique, and this in spite of his advanced age. This is the only case in this series in which an autopsy was not performed.

The diameter of the aorta is usually not greatly altered in arteriosclerosis. On occasion, slight local dilatations may occur as the result of the destruction of the elastic and muscular elements of the wall of the aorta, and rarely actual aneurism

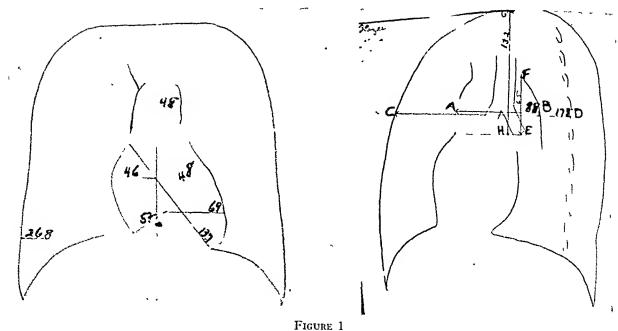

may be observed. The measurement of the transverse diameter of the aorta is often very difficult to determine from the left oblique film because of the failure of the inferior margin of the arch to outline. At times, however, this measurement can be obtained accurately, as in several of our cases. This measurement is usually best made at the descending limb of the arch.

The spatial relationships of the aortic arch within the chest cage can he determined with considerable accuracy by comparative mensuration. The elongation of the aorta produces either an increase in the height or the width of the swing of the aortic arch, or both. The effects of this elongation are easily measured in the following manner: A line is drawn from the ascending limb of the arch to the descending (outside dimensions) immediately below the transverse portion of the arch. This measurement is compared with the measurement of the chest cage taken at this same level from the right anterior chest wall to the left costovertebral articulations. If the width of the swing is within normal limits, the quotient obtained by dividing the chest measurement by the measurement of the aortic arch will be two (2) or over in most instances. This quotient, representing the transverse index of the arch, presents a range for normal individuals of 1.9 to 2.3, or over. An index below 1.9 is strong evidence in favor of aortic elongation.

A vertical index is also obtained by measuring the height of the aortic arch (above the level of the base of the heart) and comparing this with the height of the chest above this same level. The manner in which these measurements are obtained is best explained by examining the traeings of a normal aortic arch. These tracings of a youthful individual of 16 years show the general configuration of the aortic arch as observed on the left oblique film. The line AB, which represents the width of the swing of a normal aortic arch, measures 8.8 cm. The measurement CD of the chest (from the right anterior chest wall to the left costovertebral articulations) is 17.8 cm. The latter divided by the former results in a transverse index of 2.0. Similarly, for the vertical index a line is drawn from the top of the arch to the base line at the base of the heart. This is compared with the height of the chest (GH) above the base line by dividing the latter by the height of the arch EF. In the present case of the normal youth, the chest measurement is 13.2 cm. and the height of the arch 6.5 cm., which yields an index again of approximately 2.0.

A height-width index may also be obtained by dividing the height of the arch by its width. In the case of a normally proportioned arch, the two measurements of the arch are nearly equal, and hence an index obtained as a quotient approaches unity. In cases of arteriosclerosis, the index is commonly less than one (1), but because of the wide variations in normal cases this index has

Abnormal radiographic findings of this and subsequent cases were illustrated by lantern slides.

Iracings of a youthful individual showing general configuration of the acrtic arch as observed on the left oblique film.

not been found to be of much value in diagnostic work.

It now becomes of considerable interest to compare the transverse and vertical indices in cases of arteriosclerosis. In our first case (C.B.) arteriosclerosis is indicated by an elevation of the arch without any increase in the width of the swing of the arch. This was a male of 57 years, who entered the hospital with a typical history of duodenal ulcer. His heart was essentially normal on physical examination. The blood pressure was 105 mm. of mercury systolic and 65 mm. diastolic. The Wassermann test was negative.

The posteroanterior film shows relatively little except for a slight prominence of the ascending aorta and the aortic knob. The oblique film shows the typical effect of elongation with increase in the height of the swing, as indicated by an index of 1.5 (15.5 \div 10=1.5). The transverse index of the arch is normal—1.9 (19.0 \div 10=1.9). This patient died following a gastroenterostomy, and at autopsy a moderate arteriosclerosis of the arch was found. The process was more extensive in the abdominal portion, with cholesterol and calcium deposits.

Arteriosclerosis may alter the transverse index without producing any very pronounced change in the vertical index. This is very apt to occur if the process is not extensive, but is noted occasionally in relatively advanced cases of arteriosclerosis. This latter feature is illustrated by the following case (F. D.) of a woman of 61 years, who entered the hospital because of metastatic invasion of the lung by mammary cancer. The heart was not enlarged. A soft systolic blow was noted over the entire precordium. The peripheral vessels were tortuous and felt sclerosed.

The blood pressure was 184 mm. of mercury systolic and 100 diastolic. The Wassermann reaction was negative.

The posteroanterior chest film shows a prominent shadow at the aortic knob suggesting calcification, but the width across the great vessels appears within normal limits, and there is no evidence of tortuosity. The left oblique film illustrates a definitely widened swing, with a low transverse index of 1.6 (14.0 ÷ 8.8 = 1.6). The vertical index is but little altered, with an index of 1.8. The two main findings of this examination indicating arteriosclerosis are calcification and a definitely low transverse index.

At autopsy the changes in the aorta were found

to be due entirely to arteriosclerosis.

The common finding in advanced arteriosclerosis is to note a lowering in the value of both the vertical and transverse indices, and usually the latter is more profoundly altered. cases follow. The first case (J. A.) is a man of 65 years, who entered the hospital with a complaint of weakness and dyspnoea. Clinically he showed evidence of an enlarged heart (particularly enlarged to the left), a soft systolic murmur at the apex, and a diastolic murmur over the aortic area. The blood pressure was much elevated (220 mm. of mercury systolic and 130 diastolic), with a high pulse pressure. His blood showed a positive Wassermann reaction, and it was believed during his clinical course that much of the cardiovascular picture was best explained on the basis of syphilis.

The posteroanterior film shows a marked increase in the width across the great vessels, due to a prominence of both the ascending and descending aorta. The aortic knob is not prominent,

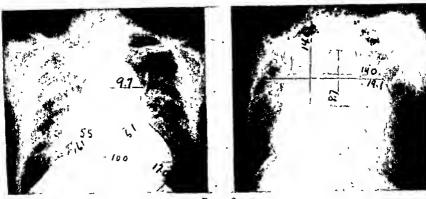

FIGURE 2
Illustrating alteration in both indices of the aortic arch

and there is no radiological evidence of calcification. The left oblique film shows an extremely wide swing to the acrtic arch, with a very low transverse index of 1.3 (19.1÷14.0=1.3), and also a fairly low vertical index of 1.6 (14.0÷8.7=16). The extremely wide swing of this arch produces a very low index; it approaches the lower limit for advanced arteriosclerosis. At autopsy an advanced arteriosclerosis without evidence of syphilis was found. The aorta was inelastic, with numerous atheromatous patches.

Similar cases, showing low transverse and vertical indices, follow. S. R. was a woman of 67 years, who entered the hospital complaining of dyspnoea, edema, and nocturia. Clinically the heart was much enlarged, with totally irregular rhythm. The peripheral vessels were thickened. The blood pressure was 170 mm. of mercury systolic, and 100 mm. diastolic. The Wassermann reaction was negative.

Examination of the posteroanterior film shows a marked increase in the width across the great vessels, with prominence of both the ascending and descending aorta. The aortic knob is not prominent, and there is no definite radiological evidence of calcification. The left oblique film shows a distinctly low transverse index of 1.4 $(17.7 \div 12.9 = 1.4)$, and a low vertical index of 16 (15.9 \div 9.7=1.6). At autopsy the arch showed numerous small atheromatous plaquesmore extensive in the distal portion. Only a slight amount of elasticity remained. The microscopic examination showed a characteristic thickening and hyalinization of the intima, without marked changes in the media or adventitia.

Case A. B. was a male of 52 years, who gave a history of precordial pain, shortness of breath, and edema for five months. Examination of the heart showed the rate to be regular and the sounds to be of good quality. There was a

systolic murmur at the apex, not transmitted. The blood pressure was 210 mm. of mercury systolic and 120 mm. diastolic.

The postcroanterior film of the chest shows marked widening across the great vessels (90 cm.). The aortic knob is not prominent. The left oblique film shows a definite increase in the width of the aortic swing (12.0 cm.), with a chest measurement of 19.0 cm. (transverse index 1.6). There is also an increase in the height of the aortic arch. This measurement is 12.4 cm., with a chest measurement of 19.5 cm. This gives a vertical index of 1.6.

At autopsy there was dilatation with hypertrophy of all of the chambers of the heart. There was also an early fibrinous pericarditis. The arch of the aorta showed numerous atheromatous patches, with some calcification Almost all of the elasticity of the aorta had been lost. The coronary arteries were not tortuous.

G. H. was a man of 62 years, whose chief complaint related to an asthma of 25 years duration Clinically the heart borders were difficult to percuss, due to emphysema. The peripheral vessels appeared sclerotic. The blood pressure was 180 mm. of mercury systolic, and 110 mm. diastolic. The Wassermann reaction was negative.

The posteronterior film shows some prominence of the ascending aorta. The width across the great vessels is not appreciably increased, although the mediastinum is displaced toward the right, probably due to the fibrotic process (Tbc.) of the right upper lung. The left oblique film is of greater interest in showing the arch and descending aorta very clearly. The swing of the arch is widened with low transverse and vertical indices of 1.8 and 1.7, respectively. The patient died suddenly as the result of coronary occlusion. At autopsy the aorta was inelastic, with numerous intimal plaques, some of which showed cal-

cification. Ulceration was also present over many of the plaques. The coronaries showed numerous plaques with calcification. The anterior descending branch of the left coronary was occluded, and an infarct was found in the left ventricle.

The last case (J. C.) was a younger individual of 51 years, who entered the hospital complaining of weakness and edema. For several years she had suffered from dyspnoea and palpitation. The heart was noted to be enlarged clinically, and over the apex a systolic and short diastolic murmur were heard. The blood pressure was 200 mm. of mercury systolic and 105 diastolic. The Wassermann reaction was negative.

The posteroanterior film shows an enlarged heart, with marked increase across the great vessels. Both the ascending and descending portions of the aorta are prominent. The knob is absent. Calcium deposit is not detected. The left oblique film shows the widened swing, with a low transverse index of 1.4 (17.5÷12=1.4). The vertical index is less affected (13.4÷7.3=1.3). At autopsy the usual findings of arteriosclerosis were present, with numerous atheromatous plaques throughout, becoming more frequent and advanced in the abdominal portion. Some of the plaques were ulcerated.

In summary, it may be said that both the posteroanterior and left anterior oblique films are of value in the identification of arteriosclerosis. A prominence of the aortic knob is not a very reliable criterion of arteriosclerosis as evidenced by its frequent absence in many cases, particularly in the cases which clinically showed evidence of hypertension. Calcium deposits are often not noted on the usual chest film, although autopsy may demonstrate its presence in abundance. The increased width across the great vessels, as noted in the posteroanterior film, may even be absent. A fair indication of aortic elongation can be obtained from an analysis of the left anterior oblique film. A low value (below 1.9) of the transverse or vertical index constitutes strong presumptive evidence of loss of elasticity. process is generalized and aneurism is ruled out, arteriosclerosis will be found to be the basis of the

pathology in most instances. Elderly individuals with syphilis may show a combination of both arteriosclerosis and syphilitic aortitis. It becomes extremely difficult to recognize both processes in such cases, unless actual eneurysmal dilatation is present. The case of D. K. illustrates this point. This patient, 54 years of age, entered the hospital because of weakness and edema. Clinically the heart was noted to be enlarged, with a systolic murmur over the aortic area transmitted downward and to the left. The blood pressure was 105 mm. of mercury systolic and 55 mm. diastolic. The Wassermann reaction was negative when non-cholesterinized antigen was used, and 3 plus with the cholesterinized antigen.

The posteroanterior film shows a marked prominence of the ascending aorta, a large but not prominent aortic knuckle, and several heavy calcium plaques of the ascending aorta and arch. The left oblique film showed a widened and elevated swing, with low transverse and vertical indices of 1.7. In this case the presence of heavy calcium plaques suggested arteriosclerosis, but the dilatation of the aorta observed in the left oblique film made a diagnosis of aneurysm very likely. Without this dilatation; i.e., in the case of syphilitic aortitis, the luetic involvement would have been entirely missed. Both the arteriosclerosis and aneurysm were verified at autopsy.

Conclusions

In conclusion it may be said that there are two main types of radiological evidence of arteriosclerosis: (a) the presence of calcification, and (b) evidence of aortic elongation. The former is often not observed on the usual chest film, even when present to a considerable degree. The diagnosis is commonly made by evidence indicating aortic elongation, such as tortuosity; a conspicuous aortic knob; or the widened great vessels of the posteroanterior film. Of particular value in gaining an estimate of aortic elongation are the transverse and vertical indices of the aortic swing as observed on the left anterior oblique film. Indices below 1.9 are commonly found in cases of arteriosclerosis.

TWO SERIES OF CASES OF FOOD POISONING

From the Departments of Pathology and Pediatries of Gouverneur Hospital.

By LAWRENCE HENRY COTTER, M.D., NEW YORK, N. Y.

THE diagnosis of "Ptomaine Poisoning" is still occasionally met with, although all careful bacteriological investigations show that these cases belong to the group of the colon-paratyphoid infections. The term dies hard. The original conception was that the protein molecule was capable of being broken down into toxic substances or "ptor.aines," which reacted

on the human system with varying degrees of violence. It is now known that the chemistry was at fault as methyl alcohol was extensively used in making the extracts and the resulting methiclates were poisonous, rather than the original constituents of the protein. The cases range from mild disability of a few hours' duration, to the fulminant and trequently fatal at-

tacks formerly labeled "Ptomaine Poisoning," and in this connection the following series occurring in the "G" family may be of interest

Case I Female child five years old, taken ill November 23, 1932, with abdominal cramps and severe diarrhea. She showed marked prostration and a temperature of 106° F within twenty-four hours of the onset, but she was kept in the house for only three days, and made a complete recovery.

Case II Female child, eight years old, taken ill November 25, 1932, and admitted to Gomer neur Hospital at 4 A M on the 26th suffering from almost continuous vomiting and diarrhea Examination showed a temperature of 107° F. heart 160, scaphoid abdomen, extreme pallor, and a palpable spleen The child was in a stupor verging on coma, and developed general convulsions with extreme opisthotonous as the temperature gradually rose to 109° and she died at midnight The total duration of the illness was 35 hours The laboratory findings were as follows WBC 23000 with Polys 85%, Lymphnevtes 14% and Monocytes 1% R B C 4,000,000 with 70% hemoglobin The stools looked like oatmeal gruel flecked with blood, and on culture showed paradysentery B Flexuer type An autopsy performed by the Medical Examiner's office revealed an acute unflamm itory colitis involving the whole colon from the ileocecal valve to the rectum

Case III Male child four years old admitted to Gouverneur Hospital on November 28th, complaining of cramps and diarrhea Examination showed a temperature of 105° F, pulse of 140, and a pulpable spleen two inches below the costal margin. The temperature gradually came down to normal, the acute stage having lasted 36 hours. The laboratory findings were as follows W B C 20,000. Polys 84%, Lymphocytes 16% R B C 4,000,000 with hemoglobin 65%. The numerous stools were of the same type as in the preceding case, and paradysentery B Flexner type was recovered on culture. The stools became negative during the ten days the patient remained under observation.

Case IV Female twelve years old, admitted to Gouverneur Hospital November 28, 1932, with a history of diarrhea for two days Her tempera ture was 100° F with a normal pulse and her physical examination reverled nothing unusual with the striking exception of a spleen easily felt three inches below the costal margin. This grad ually receded and was no longer palpable when the patient was discharged on December 9th. The white and red cell counts were within normal range, and though the stools were of the general character of those in the preceding cases, they were consistently negative on culture.

All available food used in family 'G' was cultured, particular care being given to the examination of some candy which the family was inclined

to blame for the infection, but no organism of the type found in the stools was recovered. The variation in the severity of the attack as displayed by the different members of the group was probably due to the difference in the amount of material ingested. Four members of the family who are at the common table were not affected, which ruises the question of personal immunity to the group of organisms.

The foregoing series may be profitably com pared with an outbreak affecting eleven cases which occurred six years ago. The latter were attacked simultaneously after having partaken of a meat stew about five hours previously. Nine of the eleven cases were admitted to Gouverneur Hospital at the same time, displaying the same symptoms of vomiting, diarrhea, and enlarged spleens In no case did the temperature exceed 101° F The examination of the stools gave negative results in five cases, and the Mouse Para typhoid Bacillus b was recovered from the other four It may be noted that the tenth case was admitted to Bellevue Hospital, with findings practically identical to the nine, while the eleventh was admitted to another hospital where a diagnosis of acute appendicitis was made on the physical findings, without the history of the other cases being investigated At operation the case was identified with the other ten, and the appendix was found to be normal

The stew was brought into Gouverneur by the ambulance surgeon at the same time as the patients, with the story that it had been cooked three days previously and left standing around the apartment until eaten simultaneously by the eleven B mouse paratyphoid b was recovered from it as from the four stools. The point of contact with the mouse was not clear but was assumed to have been during the period when the food was not refrigerated after being cooked.

A few general conclusions may profitably be drawn from these two outbreaks. In regard to diagnosis, the importance of the history cannot be too strongly emphasized. The enlargement of the spleen with subsequent recession presented the most striking feature of the physical examination, and in the differential diagnosis especially in ruling out the metallic poisonings it is of great value, in the absence of laboratory findings

It is significant that these outbreaks occur every year on the lower East Side of New York after a religious holiday entailing the cooking of all food some days previously to the celebrations. The most common organism to be recovered is the B Mouse Paratyphoid b, while the Flexner type is comparatively rare. Both are difficult to culture, and are rarely recovered in every case of a series and are therefore frequently overlooked. This is the explanation of infections reported as due to the Hay bacillus which may be recovered from the majority of stools, with similar saprophitic organisms.

ARRESTED SHOULDERS IN VERTEX PRESENTATION By MARK HORNSTEIN, M.D., NEW YORK, N. Y.

This is an abstract of Dr. Hornstein's paper which was published in this Journal of May 15, 1933, page 639, and is printed in order to correct figures 3 and 4, which were inverted in the printed article

of the shoulders at the superior strait of the pelvis after the head is born. The author's technique is based on the principle of transmitting the force of traction to the posterior shoulder through its trapezius muscle, thereby avoiding stretching the cervical nerves and paralysis of the arm.

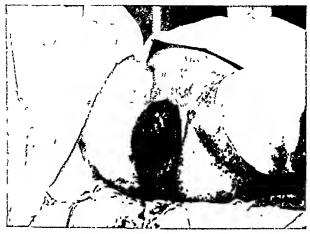

Figure 1.

All of the head, except the chin, is born in the left oeciput anterior position, with the shoulders arrested at the superior strait of the pelvis.

FIGURE 2.

Left occiput anterior position. The wrong method of delivery, consisting of restituting the head before pulling. Irrespective of which shoulder is pulled first, there is danger of brachial paralysis because the pull elongates the neek and stretches the cervical pleaus.

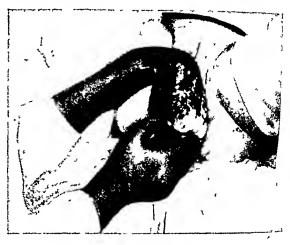

FIGURE 3.

Left occiput anterior position. The ehm has been delivered by increasing the extension of the head. The head is drawn up against the maternal soft parts by the fixed position of the shoulders at the inlet.

The figure shows the correct manner of grasping the head. The hands are crossed so that the left hand grasps the head over the occiput. The right hand five the chin. The pull of the left hand is downward and to the mother's right, thereby making the trapezius tensi The trapezius therefore transmits the force directly to the left or posterior shoulder.

FIGURE 4.

The beginning of the delivery of the posterior should. The head has been rotated so that the face looks over t left shoulder, and the force of traction is transmit along the left trapezius musele, to the posterior should which is emerging at the perineum

NECESSITIES AND LUXURIES

There are necessities in the care of the sick, and there are luvuries It is the object of medical relief to the poor to supply the medical care that is necessary, and to omit the luxuries tendency of the people in the care of their sick is to spend money on luxuries thinking that they are essential to recovery. The doctor does not object to luxuries in moderation, but he does object when the bill is greater than that for medical necessities

The doctor is willing to make liberal contributions of necessary medical service to the sick poor; but he is dissatisfied when families, friends and social workers bestow luxuries on the sick whom he treats at reduced rates The florist, the taxi driver, and the special nurse all receive their pay before the doctor is remembered. The doctor would be gratified if every dollar paid for luxuries were duplicated with an extra dollar to him for the necessities of medical service

THE PRESIDENT OF THE COUNTY SOCIETY

Physicians render medical service collectively as well as individually. When their service was rendered only to sick persons to whom they were summoned, each doctor was a complete unit in himself, and could give excellent service without regard to his colleagues. The activity of the Medical Society in those days was almost purely scientific, and the discussions in the meetings dealt with the technical work of the physician with little said about the duties of lay persons. The people expected that operations and drugs were by far the most essential agents and cures, and therefore there was little need of hospitals, or nursing, or laboratories, or other collective activities by the community.

As medical knowledge has progressed, it has reached the people to the extent that they now know the causes of sickness and realize their responsibility for seeking preventive service and providing the means of applying therapeutic measures. Hospitals, laboratories, nurses, and public medical education are among the essential services which the community must supply in order that the doctor may make an effective distribution and application of his medical skill. The rise of a popular conception of the duty of the community to place medical service within the reach of all the people is one of the most striking developments of modern medicine.

Social medical service has developed to such an extent that it has developed its own practitioners who are largely independent of the medical profession. First came departments of health and then public nurses, social workers, statisticians, endowments, and lay health associations. All these forms of organizations developed under the advice and assistance of individual physicians, while the great majority took little part in the movement. It seemed natural and proper that the people of a community should be able to organize themselves independently of the practice of physicians; but when the lay organizations began to function on a large scale, three fundamental principles became clearly apparent:

1. Every application of a medical service, preventive as well as therapeutic, is given by an individual doctor to an individual patient.

2. All methods of giving medical service satisfactory to both the patient and the physician have developed spontaneously as the result of years of experience; new ones planned on theory cannot be substituted.

3. Physicians are the medical advisers to the community as well as to the sick individual.

The practical question before the medical profession is, how shall practicing physicians as a group give medical service to a community apart from the individual sick of that community? The answer is that the County Medical Society shall be the medical adviser of the community.

This function of the County Society is now established throughout the nation, and great progress has been made in developing standard methods of giving medical advice by a County Society similar to that followed by physicians in private practice:

1. In the first place, the medical society must have its central office, which may be that of its president or its secretary; but it is essential that the existence of the office shall be widely known, and that when calls come to it they shall be answered promptly.

2. In the second place, when a call comes requesting advice, the officer receiving it shall feel a personal responsibility for answering it either personally or by assigning it to an assistant officer or committeeman.

3. In the third place, the officers of the County Society shall devise standard forms of practice, and shall develop plans for applying these forms in dealing with actual conditions in their own counties.

The president of the County Medical Society is the leader of the Society during his term of office. He is the commanding officer and the chief-of-staff of the Society. He also represents the rank and file of the members, and has his own circle of friends who are anxious to support him in his plans. He will be a busy man during his term of office; and at the end of a year or two he will yield his place of honor and service to another who will bring new ideas and enthusiasm to the office. But as an ex-president he will be able to put his experiences to use by directing the work of a committee. Service as a president of a County Medical Society is a most valuable initiation into the methods of society leadership in all forms of community medical service.

It is customary to speak of the secretary as the most essential and powerful officer of a county medical society. A secretary renders indispensable service through his knowledge of the routine work of the society and of the temperaments and peculiarities of its members. He stands for permanence of policy, for consistency of action, and for order in the proceedings of the society. His leaning is toward conservatism and the preservation of all that is good in the older methods.

On the other hand, the president is expected to try innovations and to appoint committees whose members will cooperate with him in an honest endeavor to carry out his policies. It is by a trial of innovations that progress is made.

The presidency of a county society is no longer an honor conferred for past services or personal geniality, but is an opportunity for constructive action and leadership. There is a growing sentiment to carry out this principle in the election of presidents.

MEDICAL PROGRESS

A Simple Test for Capillary Resistance: 'he "Flicking" Test,-Harold W. Jones and eandro M. Tocantins, writing in the American ournal of the Medical Sciences, April, 1933, lxxxv, 733, call attention to the difficulty that as been experienced in differentiating between n individual with purpuric manifestations and me infested with fleas. Following the bite of hese insects, petechiae and at times ecchymoses ind hematomas develop. Efforts have been nade by a number of investigators to make this distinction by means of the capillary resistance This consisted in applying a tourniquet and then making multiple punctures with a needle, after which, in certain cases, petechiae appeared. The authors have found that this test is positive in a large percentage of supposedly normal individuals. They propose the "flicking test" which is performed by applying a tourniquet two or three inches above the elbow for five minutes as for the tourniquet test. After four minutes, by flicking the middle finger against the distended vein three or four times, petechiae appear in cases of purpura. In active purpura flicking may produce petechiae in almost any part of the body. This test was performed in 108 normal individuals on whom the capillary resistance test was performed. A comparison of the two tests showed that 55 of the 108 individuals gave both negative capillary resistance and flicking tests; 33 had a negative capillary resistance test and also a positive flicking test. In each instance of a positive capillary resistance test there was also a positive flicking test. The advantages of the flicking test are that it is easy to perform, yields more positives than the capillary resistance test and is positive after the capillary resistance test is negative. In every patient with acute purpura hemorrhagica the flicking test was positive; in some of these cases the tourniquet test was negative. The positive flicking test indicates that the capillaries or venules rupture or become permeable, resulting in the appearance of petechiae. About 49 per cent of supposedly normal persons show this phenomenon in the spring of the year.

The Concept of Occupational Deformation.

—In a general medicolegal sense, says Rinaldo Pellegrini, the term deformation means exclusively an injury to the face, such as causes in those who see it a sense of repugnance. Compensation may be awarded for a deformation, provided the disfigurement limits the worker's productivity or his capacity for securing gainful occupation. Hitherto the attention of insurance companies has not been drawn to occupational deformation,

which is to be considered correlated to esthetic deformation. By occupational deformation is understood a deformity resulting from any kind of injury (due to violence in the course of work), which is expressed in an evident anatomic change such as betrays the state of incapacity of the person undergoing examination, and which, therefore, makes it reasonable to presuppose a greater or less diminution of capacity for work. It means accordingly an injury resulting in a decreased capacity for competition, and so, a lessened earning capacity, the handicap being the greater, the larger the room for choice on the part of the employer among individuals physically or productively fit. In order to constitute an occupational deformation, the injury must be by its very nature quite evident, and incapable of being concealed by any means that will not attract the attention of others. Thus there will be no occupational deformity in such cases as cardiae insufficiency from accident, large cicatrices on the abdomen, scar following incision for empyema, hernia, etc. But we shall have occupational deformation in such hypothetical cases as ankylosis in marked flexion of the limbs; amputation of a thigh or of several fingers of the hand; physiopathic contractures; claw hand, or a hand atrophic through a Dupuytren contracture or the scare of a phlegmon; tuberculous cachexia, or premature senility from accident. Especially is there a difference hetween occupational deformation in a strict sense and esthetic deformation in that, in the former there is also a real and direct incapacity for work, from anatomo-functional unfitness, while there is none in the latter. With reference to the effects of incapacity for entering into competition, occupational deformation is of much greater importance than esthetic. Consequently the percentage of damages should be estimated as greater than would be the case on the basis of a medical examination with merely biological and clinical criteria. This means that the computation of the total causes of incapacity must take into account not only the influence, in an anatomic and functional sense, that an earlier lesion, now healed, may have had upon the out-come of a later accident, but also the aggravation of an occupational deformation that may result, so that the latter takes on such a dignity as to betray itself on its own account in a diminution of earning capacity.—Riforma medica, February 25, 1933.

Atropine as a Diagnostic Aid in Appendicitis.—Francis M. Findlay states that the gradual increase in the mortality from appendicitis is largely due to delay in operation. Much

of this delay may be attributed to failure to recognize early the obstructive type of appendicitis. In this type symptoms are variable, pain being the only constant symptom. Atropine is of great value in differentiating the pain and tenderness due to acute appendicitis and that due to other In any suspected case of appendiconditions. citis, the patient, if an adult, is given 1/100 of a grain of atropine sulphate by mouth. If nausea is present it may be administered subcutaneously. One-half hour later an enema of two quarts of warm soap suds is given. After the enema is expelled the abdomen is carefully palpated, and if an area of distinct localized tenderness persists in the region of the appendix a positive diagnosis should be made. If the enema has been only partially expelled, another may be given. In the type of appendicitis due to an infective inflammation of the wall of the appendix atropine is helpful in differentiating the colic due to enteritis, colitis, or food poisoning and that due to a real inflammatory process. It is in the diagnosis of the obstructive type of appendicitis that atropine is of the greatest value, as the pain is often very transitory, and vomiting also may be absent. For these reasons an acute attack of appendicitis is often overlooked when the patient is first seen. Tenderness is frequently the only positive physical finding and failure to detect it spells disaster. Persisting tenderness over the appendix in an adult male after the use of atropine and an enema should never be disregarded. If the tenderness has been preceded by sudden onset of pain, appendicitis is present in at least 90 per cent of the cases.—New England Journal of Medicine, March 23, 1933, ccviii, 12.

Five Years' Experience with Hyperthermia Treatment.—The results of a physical method of producing therapeutic hyperthermia are reported by Franz Walinski in the Deutsche medizinische Wochenschrift of March 17, 1933. His method, published in detail in 1928 on the basis of his first experiences, consists, briefly, of giving the patient an intravenous injection of 10 c.c. of a 20 per cent saline solution, followed in 5 minutes by immersion in a bath at 37.5-38° C., the temperature of which is increased in the course of 12-30 minutes to about 41-42° C., according to the tolerance of the individual. Almost without exception the body of the patient reaches the desired thermic elevation in this time. Care must be taken not to allow it to rise too high, for fear of a subsequent unfavorable reaction to the congestion. On the first occasion it is inadvisable to allow the patient's temperature to exceed 39.5° C. The effect of the saline injection is to diminish sweat secretion, and its use (except in kidney cases, where it is contraindicated) not only causes a more rapid rise of temperature during the course of the bath, and a prolongation of its duration, but also has the distinct advantage

of nearly always making the hyperthermia more easily tolerated by the patient. After the bath the patient is immediately put to bed in a wet pack and covered with 5 woolen blankets. During the pack he is given drinks of hot tea or coffee, at a temperature 5-10° C. in excess of the body temperature. Scarcely ever has it been necessary to employ any cardiac stimulants. There has been no death among the 353 patients thus treated, whereas malaria treatment has resulted in 8-14 per cent of deaths. Patients with a blood pressure of 190 or even 200 mm. Hg have tolerated perfectly a body temperature of 40.5° C. The number and duration of the treatments must depend on the nature of the disease. In addition to increase in the blood chlorides, a simultaneous increase in the protein metabolism of the body was observed. Blood sugar values and the alkali reserve in the blood fall during the first part of the hyperthermia, to rise again later, and a leucocytosis appears in the blood picture. Diseases more or less favorably influenced were: tabes dorsalis, cerebrospinal syphilis, progressive paralysis, multiple sclerosis, postencephalitic parkinsonism, myelitis, polyneuritis, sciatica, chronic arthritis, pyelitis, bronchial asthma, and inflammatory conditions of the adnexa. No effect was observed in amyotrophic lateral sclerosis, gonorrhea (except in 1 case), herpes zoster, psoriasis, or nephritis.

The Relation of Herpetic Virus to the Results of Fever Therapy in General Paralysis. -According to O. Naegeli, the hypothesis that the presence of herpetic virus in the fever blisters accompanying fever therapy of general paralysis bears a relation to the favorable results of such therapy is based on the following grounds: Such an hypothesis is consistent with the almost exclusively regional effect of the various fever methods. Upon mobilization of the virus, a marked increase of the latter frequently occurs in the brain, and it can be readily understood that syphilis in the rest of the body would be but little influenced by a virus present there in only small quantity. The hypothesis explains clearly the uniform results in the various types of fever therapy, for these types play only the rôle of activators for the herpetic virus; the active principle, the virus, is always the same. The favorable prognosis of certain acute infectious diseases, upon outbreak of an attack of herpes, has been confirmed on the basis of experience in croupous pneumonia, by statistics covering a long period. Herpetic virus has the effect of inhibiting locally for a strikingly long time the colonization of pyococci, even in herpetic vesicles that are already suppurating. Hence it may be regarded as demonstrated that this virus must, in general, be able to influence the course of infec-The clearest tious diseases, including syphilis. and most rapid results of fever treatment, especially in progressed general paralysis and as a general rule in cerebrospinal lues, are observed in those cases in which herpes simplex has appeared during the fever. In cases in which no herpetic eruption accompanies the fever, results vary; in these, there is seldom if ever such an extensive curative result as appears in activated herpetics. However, cases have been confirmed in which there has been a cleaning up of the cerebrospinal fluid. But these are fewer than in the herpetic cases, and the somatic deterioration may rapidly increase here. Possibly the improvements may be accounted for on the supposition that there is an activation here of the herpes virus without a cutaneous cruption, perhaps in the purely neurotropic stocks. So far as ease histories can be trusted, one may conclude that there is less frequently an infection of the cerebrospinal fluid in those patients who have at an earlier period observed herpetic eruptions, especially during their syphilitic illness, than in those who never had any fever blisters. Syphilities who exhibited herpetic manifestations during the first years following infection seem to be especially protected against infection of the cerebrospinal fluid. This observation must, however, be accepted only provisionally, since such statements do not seem to be entirely reliable. The fact that the female sex is much more frequently subject to herpes simplex than the male, and that, conversely, tabes and general paralysis are decidedly less common in females than in males, appears to be of great significance in this connection. It is also true that syphilitie infection of the cerebrospinal fluid is less common in women than in men. The herpetic hypothesis may, therefore, serve at any rate to throw some light on the hitherto unexplained and very marked difference in the incidence of metalnes in males and females,-Schweizerische medizinische Wochenschrift, March 18, 1933.

Tibial Apophysitis or Schlatter-Osgood Disease.-There has never been complete agree ment, says V. Maselli, with regard to the etiology and pathogenic mechanism of the Schlatter-Osgood disease, possibly because the majority of writers have thought it necessary to commit themselves to an opinion whether a preponderant part in its causation should or should not be attributed to trauma. Maselli thinks it unnecessary to insist on this point, in view of his findings in 2 personal cases which form the basis of this study. These cases, although the symptomatology was grossly rather similar, presented entirely different anamneses and different radiological findings. In the first case the tibial lesion was bilateral, and was of pathogenetic interest because of rarefying changes observed not only in the tibiae themselves but also in other segments of the bony system as well as changes in the genital apparatus (hypogenitalism). In the second case the lesions were localized solely in one limb, where they presented all the characteristics of a detachment of the anterior apophysis of the tibia, without any change

in the consistency of the bone. The author's studies lead him to conclude that detachments or fractures of the anterior apophysis of the tibia should be considered under the single denomination of Schlatter-Osgood disease, irrespective of whether the trauma has been superadded to a constitutional lesion or has acted as the sole exciting element upon a normal bone. He proves that, contrary to the opinion of most writers, there exist cases in which the skeletal lesions are of Schlatter type, yet which differ substantially from this type in both their clinical course and the radiological picture. Such lesions, which have been regarded by some authors as constituting a single morbidentity (tibial apophysitis) are the result of various etiopathogenic mechanisms, such for example as infections from latent micro-organisms, heredosyphilis, tuberculosis, late rickets, and, as Maselli's first case shows, developmental disturbances of ossification of cartilage, probably connected with endocrinosympathetic imbalance. Treatment should in all cases be by bloodless methods, since highly satisfactory results have been obtained by immobilization in plaster casts, combined with general treatment by calcium preparations, pluriglandular extracts, or arsenobenzol, according to the etiologic judgment in each individual case.-Riforma medica, February 18, 1933.

Tannic Acid Treatment of Burns .- J. D. Martin, Jr., states that tannie acid alone is not sufficient in caring for burns, but it is a great aid when used in combination with measures for combating the toxic substance which develops following the injury. In his clinic the tannic acid method has not given the marked reduction in mortality which is reported in other clinics. However, the morbidity has been markedly reduced. The stay in the hospital has been shortened in almost every The complications treated are fewer. particularly the respiratory infections and general sepsis, and there is a lessening of scar formation Other advantages are that it lessens the pain and prevents loss of vital body fluids which escape from the wound surface. Epithelialization is hastened and the burns are much cleaner than those treated by wet dressings and some of the oily preparations. The necessity of frequent and painful dressings is removed, which is an important economic factor. In extensive burns the first consideration is the treatment of primary shock. Morphine is administered in doses sufficient to make the patient comfortable. External heat is applied by the use of blankets and a canopy with electric light bulbs. Stimulants are administered early. An infusion of 1000 c.c. of normal saline is given immediately and is repeated every six or cight hours. Saline and glucose are administered routinely. When the patient has reacted from the shock, all loose skin is removed and the surface cleansed with saline or some mid non-irritating antiseptic. An aqueous solution of

2.5 to 5 per cent tannic acid is then applied to the surface by an ordinary atomizer every thirty minutes until a good tannate is formed, which usually requires from six to eighteen hours. In first and some second degree burns the coagulum begins to come away in eight to twelve days, leaving a dry layer of epithelium. In deeper burns the tannate must be removed, usually by softening the edges with dichloramine gauze and wet dressings of saline. After all the coagulum is off the raw surface is prepared for grafting by applying saline dressings. The most comfortable procedure is to place the patient in a tub of warm water two or three times daily for twenty to thirty minutes. All burns should be grafted rather than allowed to heal by granulation. During the entire treatment consideration must be given to the position of the patient in order to prevent contractions.— Southern Medical Journal, April, 1933, xxvi, 4.

Lead Poisoning and Gastric Ulcer.—The possibility of an etiological relationship between lead poisoning and gastric ulcer is discussed by Albrecht Peipers in the Deutsche medizinische Wochenschrift of February 17, 1933. The question has more than an academic interest, since upon its answer hinges the patient's right to claim compensation under the social insurance laws. An illustrative case history is presented, of a locksmith, aged 46, who after working for 10 years upon lead castings with hammer and chisel, began to suffer with abdominal pains, which were diagnosed by the house physician at the Marburg University hospital as lead poisoning—a diagnosis which was later confirmed by the industrial physician on the basis of anemia, a blue line on the gums, and stippled erythrocytes in the smear. An application for compensation made somewhat later on grounds of chronic lead poisoning was denied, since an official examination, although revealing signs of vegetative stigmatization, failed to demonstrate the persistence of any typical signs of lead poisoning. An x-ray examination the following year for colicky pains and vomiting with which the patient had suffered for two years, revealed the presence of a duodenal ulcer and signs of spasm of the colon. Schiff in a little known work pointed out in 1919 that in chronic saturnism, in addition to typical colics, there also appear uncharacteristic conditions of pain, of long persistence. From the debate with reference to the genesis of ulcer, 2 principal causes emerge: (1) a circulatory disturbance, and (2) a disturbance in the balance of the peptinizing capacity of the gastric juice and the antipeptic defence of the gastric wall, or of the blood. The pathologicanatomic findings of muscular hypertrophy, thickening of the connective tissue of the vessel sheaths, and obliterating processes furnish a sufficient morphological basis for the assumption that circulatory disturbances are of significance in the

pathogenesis of ulcer in victims of lead-poisoning The objection might justly be raised that in comparison with the frequency of ulcers the coincidence with lead poisoning is purely accidental. But in the case cited the author thinks it is justifiable to assume a connection between the two diseases, for to him the fact was decisive that the pains had first put in an appearance after the time at which the lead colic clinically appeared. Chronic lead poisoning may, as the above shows. produce conditions that bring about an ulcer even in an individual in whom no dysharmony of the vegetative system existed. Moreover, the coincidence of ulcer and manifest lead poisoning has been observed not infrequently by various authors.

The Resistance of Healing Wounds to lafection:-In order to determine the degree oi infectibility of simple incised and sutured wounds, Jean Jacques DuMortier swabbed such wounds with a culture of pathogenic organisms after various intervals of time. He found that the resistance of a healing wound to infection is minimal during the first six hours. After the first six hours, infections decrease in number and severity When organisms are imuntil the fifth day. planted upon a sutured wound twelve hours after operation, although the great majority of incisions become infected (83 per cent), the infections are localized. From this time on, the percentage and severity of infections steadily decreases until, between the fourth and fifth postoperative days it is no longer possible to cause infection by implantation of virulent microorganisms on the surface of the wound. This period of four to five days corresponds with the "lag period" of healing wounds, described by Harvey and Carrel. This period is characterized by fibrin formation in the blood or plasma exuded between the surfaces of the fresh wound. This fibrin formation apparently has but little resistance against the invasion or multiplication of bacteria and it is only when it has been replaced by fibroblasts that protection against bacterial invasions becomes complete. It is of clinical importance that for the first five days following an operative incision extreme care be taken in the manipulation of a wound. Removal of the stitches on the sixth day after operation does not lower the resistance of the wound to infection, since these stitches have become walled off by granulation tissue, which is highly resistant to the invasion of bacteria. The author points out that the period in healing, in which a wound may be manipulated without danger of resulting infection through surface implantation of organisms, whether by wilful of unintentional abandonment of the principles of asepsis, has not hitherto been demonstrated. Surgery, Gynecology and Obstetrics, April, 1933. lvi, 4.

LEGAL

JURORS-MISCONDUCT HELD CONTEMPT OF COURT

By Lorenz J Brosnan, Esq. Counsel Medical Society of the State of New York

It is absolutely essential to the proper administration of justice that those who are called upon to serve as jurors conscientiously and honestly perform the duties of their office. A juror who violates his oath of office strikes at the very foundation of our government. He commits a serious offense for which he can, under our law, and should receive punishment. An example of a statute designed to safeguard litigants against "jury fixing" is found in Section 753 of our Judiciary Law which provides for punishment of contempts of court, and deals with improper conduct of jurors as follows.

"Sec 753 subd 6 A person duly notified to attend as a juror, at a term of the court, for improperly conversing with a party to an action or special proceeding to be tried at that term or with any other person, in relation to the merits of that action or special proceeding, or for receiving a communication from any per son, in relation to the merits of such an action or special proceeding, without immediately disclosing the same to the court"

The United States Supreme Court recently passed upon a most important case involving a question of the validity of the ruling of a trial judge punishing a juror for misconduct der to understand the ruling of the court it is necessary to discuss the facts in detail. In one of the Tederal District Courts a certain defend ant F--- was indicted for use of the mails to defraud, and when his case came up for trial a panel of jurors was summoned to attend jurisdiction was one in which women have the privilege and duty of serving as jurors and a certain Mrs C- received a notice first made inquiries as to how she might be excused from jury duty, and learned that excuses should be presented to the judge and further that she probably would not be accepted as a mror for the trial of Γ — as she had once been in the employ of the F- Company, with which the defendant lind been associated

She reported at the courtroom the day of the trial and while other members of the jury were being examined she stated to several other women on the panel that she wanted to serve on the jury, but that she was afraid that she would be disqualified because of her former employment. The facts were that she had been for a short time a stenographer and typist in the employ of

the F—— Company, and that in addition she had been for a few years assistant eashier in a bank of which F—— had been an active customer Mis C—— had married the president of the stud bank, and a friendship of some years standing had existed between Mr C—— and F——

When Mrs C-was interrogated under oath on her so-called tour dire examination to deter nune whether she was suitable and satisfactory as a juror, she was asked if she had ever been in business of any kind. Her answer was, "I have been a stenographer before my marriage, yes" In answer to a question as to the kind of business, she said, "Well, I did some banking and some real estate and insurance and I was with an automobile concern, with a Nash agency' Upon being asked whether she felt that she was unbiased, and that she could base her verdiet upon the evidence, and the law given her by the court, she replied that she was unbiased and would follow only the evidence and the law Rehing upon these answers the prosecution accepted her as a juror and she sat as such during the entire trial, which lasted eight weeks

The court submitted the issue of the innocence or guilt of the defendant to the jury and after deliberating for a full week the jury reported their inability to agree and were discharged. The jury stood eleven to one in favor of conviction of the defendant. The sole vote for acquittal was that of Mrs C--- It was brought out that during the trial Mrs C--- had told the jurors that she regarded F--- as a victim of circum stances, he having been unable to borrow money to cover his needs in the year 1929. She had told the other jurors that the source of her information was outside the evidence. During the jury's deliberations she refused to reason with the others, placing her hands over her cars or failing to reply to their statements them that a certain witness for the prosecution was a perjuror and that she had been told so by her husband

The government took steps against her to punish her for contempt, charging that her answers on the voir dire examination had been wilfully and corruptly false, and that her misconduct had hindered and obstructed the trial. A hearing on these charges was held and after such hearing the court found Mrs. C——guilty of obstructing the administration of justice by falsely stating that she was free from bias and would follow the

law and the evidence, and in deliberately concealing the fact of her employment with the F——Company. She was thereupon sentenced to fine and imprisonment.

The case was then taken on a writ of Certiorari to the United States Supreme Court where the conviction was affirmed. The opinion of the court was delivered by Justice Cardozo.

The opinion stated that the jury woman had been properly found guilty of both false swearing and concealment, but that the wrong that she was being punished for was that of improperly intruding into a position for which clearly she had believed herself ineligible and thereby to obstruct the administration of justice. The court stated:

"The petitioner is not condemned for concealment, though concealment has been proved. She is not condemned for false swearing though false swearing has been proved. She is condemned for that she made use of false swearing and concealment as the means whereby to accomplish her acceptance as a juror, and under cover of that relation to obstruct the course of justice. There is a distinction not to be ignored between deceit by a witness and deceit by a talesman. A talesman when accepted as a juror becomes a part or member of the court. . . . The judge who examines on the voir dire is engaged in the process of organizing the court. If the answers to the questions are wilfully evasive or knowingly. untrue, the talesman, when accepted, is a juror in name only. His relation to the court and to the parties is tainted in its origin; it is a mere pretense and sham. What was sought to be attained was the choice of an impartial arbiter. What happened was the intrusion of a partisan defender. If a kinsman of one of the litigants had gone into the jury room disguised as a complaisant juror, the effect would have been no different. The doom of mere sterility was on the trial from the beginning."

The argument had been urged on behalf of Mrs. C— that what had transpired in the jury room was privileged, and had been improperly used against her. The court dealt with the said argument by ruling that even assuming such a privilege to exist in ordinary cases, in this case it had been lost for the petitioner had assumed her duties as a juror through fraud, and there-

fore was not entitled to benefit by the immunities of jurors.

It had been urged that to hold Mrs. C—for contempt would tend to deprive jurors of their views and would cause them to fear punishment for following their own views on any given case. The court disposed of those arguments as follows:

"A juror of integrity and reasonable firmness will not fear to speak his mind if the confidences of debate are barred to the ears of mere impertinence or malice. He will not expect to be shielded against the disclosure of his conduct in the event that there is evidence reflecting upon his honor. The chance that now and then there may be found some timid soul who will take counsel of his fears and give way to their repressive power is too remote and shadowy to shape the course of justice. It must yield to the overmastering need, so vital in our polity, of preserving trial by jury in its purity against the inroads of corruption."

The court continued:

"She has not been held to answer for any verdict that she has rendered, nor for any thing said or done in considering her verdict. She has been held to answer for the deceit whereby she made herself a juror, and was thereby placed in a position to vote upon the case at all. What was said and done in the jury room is not the gist of her wrongdoing. What was said and done in the jury room is no more than confirmatory evidence of her state of mind before. . . . Indeed what happened in the jury room added so little to the case that the error, if there had been any, in permitting it to be proved, would have to be regarded as unsubstantial and without effect on the result. No one can read the findings of the triers of the facts and hesitate in concluding that even with this evidence omitted there would have been an adjudication of contempt. In considering with all this fullness the merits of the ruling. we have been moved by the desire to build securely for the future."

Every citizen who is interested in the proper administration of 'our law will heartily concur with the opinion of the highest court of our land. It is to be hoped that the punishment to this juror will serve as a warning that such conduct will not go unpunished.

CLAIMED NEGLIGENT APPLICATION OF ARGYROL TO THROAT

A doctor was requested by a patient to examine her throat as she complained that it was giving her considerable discomfort. The doctor found her throat slightly red with a post-

nasal discharge. He took a tongue depresson and a throat applicator, and after applying clean cotton on the applicator he dipped the same in 25% argyrol solution and applied it

to the nasopharynx. On doing so the doctor observed that a few drops of blood came from the sensitive mucous membrane. The patient however seemed to suffer no discomfort, except that she coughed a few times. She left the doctor's office and the next he heard of her was when he received a telephone call the following night stating that the patient was suffering from a hemorrhage. He called at her home and found that she was bleeding somewhat from the nasopharynx. He cleaned a clot of blood away from the area and applied adrenaline solution and gave her an injection in the arm to promote coagulation of the blood. The next day he again received a call that the blood was again bothering the patient and he directed that she should enter a hospital where she remained a short time receiving care for her condition which promptly improved under his treatment.

An action was instituted charging the doctor with malpractice in his treatment. The charge was that in treating the patient's throat the doctor had negligently cut or picrced one of the main arteries. Said claim, of course, was emphatically denied by the doctor. The case came on for trial and the plaintiff was unable to introduce any competent proof to the effect that anything the doctor did or failed to do was improper. Thereafter, at the close of the plaintiff's testimony, on motion of defendant's counsel, the complaint was dismissed, finally terminating the matter in favor of the doctor.

EPILEPTIC SEIZURE DURING TREATMENT

A specialist in ear, nose and throat cases was consulted by a young man who complained of nose trouble. The doctor examined him and found that he had chronically infected tonsils and a chronic infection of the left sinus. The doctor advised the application of eph-

edrine by drops in the nose.

The patient returned about two weeks later and at that time the doctor intended to give him a treatment preliminary to which he swabbed the patient's left nostril with adrenaline. The doctor left the patient sitting on a chair attended by his nurse, and stepped a few feet away for the purpose of obtaining his instruments in order that he might proceed with the treatment. Just at that moment the patient made a remark to the nurse that he felt weak and the nurse ob-tained a bottle of smelling salts consisting of ammonium carbonate crystals. She removed the cork and was just about to put the bottle to the patient's nose when the patient suddenly went into an epileptic fit, rolling from the chair down onto the floor. he fell he in some way struck the nurse's hand in which she held the open bottle of crystals and some of these spilled out over the patient's face, one or two of them going into his eyes. The doctor immediately took steps to restore the patient to a normal condition and he promptly seemed to become normal except that both of his eyes showed signs of redness. The doctor applied boric acid solution to the eyes and told the patient that if his eyes bothered him further he should go to an eye man for treatment.

Apparently he did go to another doctor who examined his eyes and found a condition of crosion of the cornea which after treatment with medications entirely healed and the man's eyes became perfectly normal in a few weeks,

A suit was brought against the doctor, charging him with negligence in the matter, claiming that the doctor or his assistant while treating the patient had so negligently mishandled a certain chemical as to cause it to be thrown or spilled into the plaintiff's eyes, thereby causing him to sustain severe burns in both of his eyes with a resultant inability to attend to his vocation for one month. The case came up for trial before a Judge without a Jury and after the testimony had been put in on both sides the Judge directed a judgment in favor of the defendant doctor.

NEWS NOTES

EXECUTIVE COMMITTEE

The regular monthly meeting of the Executive Committee of the Medical Society of the State of New York was held in the State Society rooms. 2 East 103rd Street, New York City, on Thursday, May 11, 1933. The following officers were present:

Frederick H. Flaherty.
Samuel J. Kopetzky.
Chas. Gordon Heyd.
Daniel S. Dougherty.
Louis A. Van Kleeck.

Arthur J. Bedell.
Thomas P. Farmer.
James M. Flynn.
Stuart B. Blakely.

The following appointments were made: Orrin Sage Wightman, Editor-in-Chief. Frank Overton, Executive Editor. Lorenz J. Brosnan, Legal Counsel. Thomas H. Clearwater, Attorney.

The reappointment of J. S. Lawrence as Executive Officer was approved and referred to the Trustees for a renewal of his contract.

Dr. Terry M. Townsend of New York was appointed Chairman, and Dr. Thomas F. Laurie of Syracuse, Secretary, of the newly created Section on Urology.

The President submitted a list of nominees to complete the Standing Committees, their chairman having already been elected by the House of Delegates. These nominees were elected. The complete personnel of the standing committees is as follows:

STANDING COMMITTEES

COMMITTEE ON SCIENTIFIC WORK

William A. Groat, Syracuse, Chairman. Alfred M. Wedd, Clifton Springs. Floyd S. Winslow, Rochester. Milton G. Potter, Buffalo. Adolph G. De Sanctis, New York. Frank M. Sulzman, Troy. Stanley W. Sayer, Gouverneur. Leon H. Cornwall, New York. George M. Fisher, Utica. Terry M. Townsend, New York. Joseph M. Steiner, New York. William F. Jacobs, Buffalo.

COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

Thomas P. Farmer, Syracuse, Chairman. George W. Kosmak, New York. Mahlon H. Atkinson, Catskill. Leo F. Schiff, Plattsburg. William A. Groat, Syracuse. Martin B. Tinker, Ithaca. Clayton W. Greene, Buffalo. Edward G. Whipple, Rochester. Nellis B. Foster, New York.

COMMITTEE ON LEGISLATION

Harry Aranow, New York, Chairman. John J. Buettner, Syracuse. Bernard B. Berkowitz, Brooklyn. B. Wallace Hamilton, New York. Edward E. Haley, Buffalo.

COMMITTEE ON ECONOMICS

Frederic E. Elliott, Brooklyn, Chairman. Charles H. Goodrich, Brooklyn.
Frederick M. Miller, Utica.
Frederick S. Wetherell, Syracuse.
Joseph O'Gorman, Buffalo.
Joseph Garen, Olean.
Cassius H. Watson, New York.
Terry M. Townsend, New York.
George C. Vogt, Binghamton.
Edward T. Wentworth, Rochester.

COMMITTEE ON PUBLIC RELATIONS

James E. Sadlier, Poughkeepsie, Chairman. William H. Ross, Brentwood. George M. Fisher, Utica. Oliver W. H. Mitchell, Syracuse. Augustus J. Hambrook, Troy. William D. Johnson, Batavia. Thomas H. Cunningham, Glens Falls.

SPECIAL COMMITTEES

The nominations of the President of the following members of the Special Committees, were confirmed:

COMMITTEE ON PUBLICATION

Frederic E. Sondern, New York, Chairman. Peter Irving, New York. Louis A. Van Kleeck, Manhasset.

COMMITTEE ON BUDGET

Chas. Gordon Heyd, New York, Chairman. Frederic E. Sondern, New York. Daniel S. Dougherty, New York.

COMMITTEE ON MEDICAL RESEARCH

John J Morton Jr Rochester Chairman
John Wyckoff New York
Joshua E Sweet New York
Allen O Whipple Kew York
G Canba Robinson New York
Simon Flexner New York
Peyton Rous New York
Augustus B Wadsworth Albany
Edwin MarcD Schuton Schenectady
Herman G Weiskotten Syracuse
Winfield W Scott Rochester
Burton T Simpson Buffalo
Frank A Hartman Buffalo
Varshall Clinton Buffalo

COMMITTEE ON INSURANCE

Frederic E. Sondern New York Chairman Chas Gordon Heyd New York Louis A Van Kleeck Manhasset

COMMITTEE ON PRIZE ESSAYS

James Ewing New York Churman Allen O Whipple New York Leon H Cornwall New York

COMMITTEE ON BY LAWS

Daniel S Dougherty New Yorl Chairman Thomas P Farmer Syracuse acting with the Legal Counsel Lorenz J Brosman

COMMITTEE ON TEMPORARY LMLRGENCY RELIEF

THE 1933 GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

Metabolic disorders will be the theme of the 1933 Graduate Fortnight of the New York Academy of Medicine Two weeks of intensive study, from October 23 to November 3 inclusive, will be devoted to this important branch of medical science. The theoretical physiologic and pathologic phases of Metabolism, as well as of certain of the associated endocrinologic problems will be treated in a series of round table discussions and clinical demonstrations. The latter will be given in fifteen of the leading hospitals of New York City

Among the speakers who will participate in the Graduate Fortnight are included Drs Eugene F DuBois, Harold E Himwich Walter W Palmer, Frank H Lahey, Donald Dexter Van Slyke, Joseph C Aub, Ashley Weech Dani W Atchley, Erwin Brand Emanuel Libman, Rollin T Woodyatt, Priscilla White Nellis B Foster, Herman O Mosenthal, William S Ladd, Henry W Geyelin, Albert A Epstein, John P Peters, Henry C Sherman,

Samuel W Clausen, Alfred F Hess, Wilder G Penfield, Oscar M Schloss, Henry L Jaffee and Charles F Bodecker

An exhibit will be shown in connection with the Fortnight, material having been collected from many institutions in Metropolitan New York. The various aspects of metabolic disorders will be covered in this exhibition in cluding the history of inctabolism, dietary constituents and their derivatives, drug and other therapeutic measures, general and special pathological metabolism, and laboratory methods and procedures.

The subjects will be illustrated by means of charts, graphs, photographs, microphotographs, transparencies, trays and gross and pathologic specimens

The profession of the country is invited to participate in the Graduate Fortnight

A complete program and registration blank may be secured by addressing Dr Frederick P Reynolds, The New York Academy of Medicine, 2 East 103rd Street, New York City

GREENE COUNTY

The regular May meeting of the Greene County Medical Society was held in the Saulpaugh Hotel in Catskill on Tuesday, May 9, 1933, with twenty members and guests present. The President, Dr. L. B. Honeyford, Catskill, presided and introduced the speakers of the evening, Dr. Frederic Holcomb, and Dr. Joseph Jacobson, both of Kingston.

Dr. Holcomb's address was devoted to the various classifications of tuberculosis and their These classes were illustrated by

many x-rays of each kind.

Dr. Jacobson's address was confined to the

operative measures employed in treating tubercu-This also was profusely illustrated by x-rays.

Dr. Atkinson, Chairman of Committee on Memorial Tablet for the new hospital reported that the draft as presented had been accepted by the Board of Managers and that the tablet had been ordered.

Dr. William V. Wax of Catskill was elected to membership. It was decided to hold the July meeting as usual at the Catskill Mountain House,

WILLIAM M. RAPP, Secretary.

SCHOHARIE COUNTY

The semi-annual meeting of the Schoharie County Medical Society was held in the Parrott House, Schoharie, New York, on Tuesday, May 9, 1933. Dr. Bentley reported that no legislation affecting us seriously, was enacted. Our Delegate, Dr. D. W. Beard, gave a short report of the meeting of the State Society. A committee on relations between the welfare agent and physicians was appointed consisting of Drs. H. R. Bentley, D. W. Beard and D. L. Best who are also to arrange a suitable and acceptable fee bill.

The following officers were nominated:

President......Dr. Roy G. S. Dougall Vice President......Dr. Duncan L. Best Treasurer......Dr. Le Roy Becker Secretary......Dr. Herbert L. Odell Censor......Dr. Willard T. Rivenburgh Delegate......Dr. David W. Beard

After a lengthy debate on the selection of another list of names to submit to the Chairman of the Board of Supervisors from which list one is to be appointed a member of the county board of beer control, the Comitia Minora was empowered to submit such list, each member of the society being requested to suggest one or more names for the committee to consider.

After adjournment for dinner, the society listened to a paper on "Sinus Conditions from the Standpoint of the General Practitioner," by Dr. Harry K. Tebbutt, Albany, N. Y. A rising vote of thanks was given Dr. Tebbutt for his excellent and practical address.

The attendance was large, nearly all members being present.

H. L. ODELL, Secretary.

TIOGA COUNTY

The Tioga County Medical Society completed a Post-Graduate series, consisting of five lectures, arranged by Dr. Clayton W. Green of Buffalo and delivered by Dr. Green and his associates, Dr. A. H. Aaron, Dr. N. G. Russell, Dr. E. H. Heath, and Dr. E. A. Sharp.

This was a very fine course and of great interest to the general practitioner. The meetings were held weekly, as dinner meetings, and we had an average attendance of twenty-eight Doctors per meeting, whereas our County Society Membership is twenty-two.

At the final lecture, we had an open meeting in which the wives of the Doctors and other guests were invited, and had a total attendance of fifty-seven persons.

The members of the Society consider this one of the most practical courses that they have

enjoyed.

G. S. CARPENTER.

BROOME COUNTY

Economics A special meeting of the Broome County Medical Society, convened on February 15 1933, for the purpose of discussing current economic problems and other business matters Much stress was placed on the proposed New York Retail Sales Tay It was discussed with unusual activity and the Society went on record as emphatically opposing any further increased taxation in New York State at this time, the tax burdens already being at a distressing maximum

and the Retail Sales Tax being an additional taxation with no displacement of the taxes already existing. The Society further recorded itself as urging the officials of New York State to practice more economy in the State government affairs, feeling that the time has arrived for conservatism and the cessation of extravagance in governmental departments.

HENRY D WATSON, Secretary

WASHINGTON COUNTY

A meeting of the Medical Society of the County of Washington was held on May 9, 1933, in Fort Edward Twenty one members were present

A resolution was proposed giving our standing regarding the appointment of names for the beer control President Macarthur read communications from Dr. I awrence and Governor Lehman's Secretary, and a special telegram from the President of the State Society concerning it

After much discussion this was tabled and no

nominations were made

Dr W A Leonard reported as churman of the Legislative Committee He was given a vote of thanks for his efficient work as chairman of this committee

Dr S J Banker made a motion that we still retain the present fee list with the understanding that the members who had reduced their fee did it for the present emergency only. It was see

nuded and carried (See this Journal, May 15, page 663)

Dr E V Farrell, of Whitehall gave a paper on "Functional Digestive Disorders" Dr B Deifendaufer, representing the State Department of Health, read a paper on 'Frichmosis,' and stated that there were six cases in Washington County recently, and that two per cent of all logs killed were infected. The symptoms appeared from 14 to 25 days after the infected meat was eaten. They were clulls, fever, diarrhea, and the special symptoms were edema of the face and soreness in the muscles.

Dr R E Borrowman of Fort Fdward gave an address on "Pseudo Hermaphrodism" and presented a case Dr E B D Elliot of Glens Falls talked on "Intracranial Hemorrhage" in the new born

S J BANKER Secretary

DUTCHESS-PUTNAM COUNTY SOCIETY

A regular meeting of the Dutchess Putnam Medical Society was held Wednesday, May 17th, 1933, at the Chimney Corner, Poughkeepsie N Y The meeting was called to order by the President Dr Samuel E Appel at 8 50 P M

The minutes of the previous meeting and the minutes of the Comitia Minora meeting were read and approved

The following candidates were received

Dr Louis A Parsell

Dr Frank C Genovese by transfer from Queens County

Dr James P Kelleher by transfer from New York County

Doctor A W Thomson gave a preliminary report of the Economics Committee

Doctor James T Harrington reported progress in the formation of an arbitration commission

It was regularly voted that the next meeting of the Society be devoted to the consideration of economic affairs

Dr Samuel Goodwin Gant, New York City, the guest speaker of the evening gave an address on "Bengin and Malignant Tumors of the Recto

Sigmoid'il Region"

The meeting adjourned at 1045 PM for refreshments, during which Dr Gant mystified the dictors with his feats of Medical Magic There were present Drs Appel Thomson, C E Lane, Borst Dingman Marks, Peckham, Voorhees Rogers, Neighbors, Parsell, Davison, Benson, Roberts Poucher, Vigeant, Andrews Stoller, Ashley, Harrington, Lynn, Cavanaugh, Mombello, Carpenter, Sinion, Breed, Myers, Penn Palliser Krieger, Leonidoff G MacKenzie, Popp Sobel, Rosenthal Bacile, Crane, Haas, G E Lane

H P CARPENTER M D, Secretary.

OUR NEIGHBORS

DEPARTMENT OF HEALTH AND PHYSICIANS IN INDIANA

The leading article in the May number of the Journal of the Indiana State Medical Association was prepared by Executive Committee of the State Association on the subject "Reorganization of the Indiana State Board of Health," which sets forth the relations of the physicians to the Board, under plan of reorganization accomplished by Governor Paul V. McNutt. The following abstracts indicate the scope of the new relations:

"There is no need to disguise the fact that there has been, in times recently passed, considerable cause for criticism of the broadening activities of this branch of government. Attention has been particularly directed toward the work of the Division of Infant and Child Hygiene, the Hygienic Laboratory, and the subsidization of the Venereal Clinics in different cities of the state. Not only have these branches cost a considerable sum of money, but they have also entered into forms of medical practice which have essentially put the state in competition with the practitioners of medicine. The manner in which the work of these departments is to be carried out is described later in this article.

"The present set-up is designed to correct these abuses, improve the quality of the proper services of the State Board of Health, and to effect a saving of probably \$75,000 a year."

After describing the heads of the departments which had been appointed after consultation with the State Association, the authors took up the work of the bureaus and said:

"The work of the Pasteur laboratory will be under the direction of Dr. Culbertson, Director of the Laboratory of Hygiene, but the actual giving of the Pasteur treatment will be done in the admitting room of the Long Hospital. By this means these patients will be in such a place as can properly take care of them in case their dog-bite wounds should need attention, and also in case they should get reaction from the treatment. These patients who come from a distance are required to be housed and fed by the state. In the vicinity of the Medical School campus there are many private homes where the owners would be glad to rent rooms to these patients at a very low cost.

"The attention of the profession is called to the fact that there is a provision whereby patients can be treated in their home communities by their own doctors, in the same way that they can be given free anti-toxin by their home physician. The new organization emphatically urges that all communities be responsible for the treatments of persons bitten

y dogs.

"The work of the Division of Infant and Child Hygiene is to be discontinued, except in its strictly educational phase. The new organization is extremely anxious that the interest of the public in these matters should be encouraged; and as need arises for educational programs, the medical profession and the University School of Medicine will stand ready to supply talent for such work. The communities under the leadership of the county medical societies are urged, however, to take the initiative in all of this work. Neither the State Board of Health nor the State University wishes to force anything of this sort upon a given community, but is glad to co-operate through the medical society in every way possible with clubs, parent-teacher associations, and other groups qualified to carry on such work. In all such activities the local medical association will be consulted before action is

"A strenuous effort will be made to discourage the use of the laboratory except for the two purposes for which it was originally designed, namely, the control of transmissible diseases, and the provision of a service for the indigent sick. In order that the interests of the medical profession shall be observed, a dual committee has been appointed. Three men will represent the Board of Health and the University, and three other men will represent the State Medical Association. It will be the purpose of this committee to arrange working rules for the laboratories.

"State support for venereal clinics is to be withdrawn. There is no doubt whatever that the venereal diseases are extremely important public health problems. It is the desire of the new organization, however, to place the responsibility for those problems exactly where it belongs; that is, in the home community. If a particular town or county wishes to establish such clinics, the organization will be only too glad to be of assistance.

"For several years the State Board of Health, the State University School of Medicine, and the State Medical Association have been more or less at cross purposes. Such a condition is most improper and to be lamented.

A Physiological Laxative and Digestant WYALIN

Stimulates Flow of Bile Aids Digestion Helps Correct Putrefaction

The newest Wyeth development—Wyalin—is already receiving favorable comment from physicians. They find it not only rational in theory, but effective in practice.

Wyalin combines the hepato-biliary stimulant effect of bile salts and pancreatic enzymes and, as such, may be described as a physiological laxative and cholagogue.

The general tonic laxative effect has been augmented by the addition of small doses of nux vomica and aged cascara extracts.

Used in the treatment of bowel hypo-motility due to biliary insufficiency, Wyalin helps promote the freer flow of bile, aids in the more complete digestion of fats, combats putrefaction.

Wyalin is proving an effective form of drug treatment in cholangitis and cholecystitis.

Supplied in packages for prescription use, each containing 50 tablets of a distinctive color and shape.

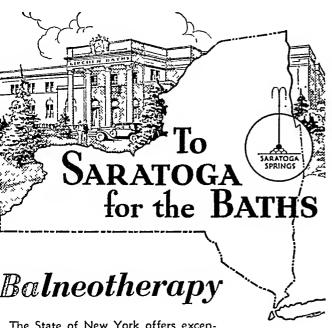

May we send you a sample package of Wyalin for a clinical trial test?

Control the integrity of your prescriptions by specifying Wyeth's pharmaceuticals.

JOHN WYETH & BROTHER, Inc.

PHILADELPHIA, PA. AND WALKERVILLE, ONTARIO

The State of New York offers exceptional facilities for balneotheapy and collateral treatments at Saratoga Spa.

The baths are made possible by the naturally carbonated mineral waters of the Saratoga area. These waters have been characterized by leading scientists as the peers of any to be found in Europe and are the only such waters found in the United States east of the Rocky Mountains.

The use of these baths has been found highly valuable in cardiac therapy and is indicated also for gout, muscular rheumatism, arthritic and neuritic conditions, and obesity.

Hotel and housing accommodations, with special dietary service, are available in Saratoga Springs. The air is invigorating, the surroundings quiet and restful. Bathing establishments are conveniently located.

Owned and Operated
BY THE STATE
OF NEW YORK

(Continued from page 716)

As short a time ago as the last state meeting the situation seemed to be one that was for from solution, though resolutions pointing of the desirability of making some change were passed. The reorganization under Governo McNutt offers a marvelous opportunity to confect the difficulties. As a matter of fact, the Governor has consulted physicians in considerable number, and is very anxious to do what

is right in this connection.

"The University is taking no part whatever except that it will lend the services of it scientific staff to the Board of Health for scien tific and educational purposes only. The University will have nothing to do with the enforcement of laws or the various police functions of the Board of Health. All laboratories and offices will remain in the old location and the relation of the University will be such tha at any time it will be a very easy matter to the University to drop out of the picture. Th only purpose of that institution is to give a at a time when aid is greatly needed. Under no circumstances will the University becom aggressive, or attempt to exercise influence political pressure. Likewise, it will not a tempt to determine the policies of the Boar of Health or the medical profession.

"The new organization believes that this the biggest step that has ever been taken Indiana away from state medicine."

GRADUATE EDUCATION IN KENTUCKY

A series of graduate lectures in obstetrics und the auspices of county societies is described the March issue of the Kentucky Medical Joi nal as follows:

"Arrangements have been made for a series postgraduate lecture courses, at different points Kentucky, by Dr. J. R. McCord, Professor Obstetrics, Emory University, Atlanta, Georgia

"The first of this series, seven in number, v be delivered in Louisville, April 3-7, in the amp theatre at the City Hospital. The lectures will given on five consecutive afternoons, between t and five o'clock. All physicians in surround counties are cordially invited to attend by the J ferson County Medical Society, which is sponsing the course.

"On the evening of March 20th, Dr. McCo will speak at the regular meeting of the Jeffer. County Medical Society, as a guest of the Lot ville Gynecological and Obstetrical Society.

"On April 17-21. Dr. McCord will give the s ond of his series of lectures in Paducah, under auspices of the McCracken County Medical ciety. It is expected that these lectures will

(Continued on page 720-adv. xii)

to overcome the marked mineral depletions caused by such acute infections as acute bronchitis, coryza, the debility of old age, and postoperative conditions.

Fellows' Syrup contains all the essential elements in a perfectly balanced solution. Unbalanced cell metabolism induced by a depleted mineral content is speedily overcome when these elements are supplied in a form which the body can readily assimilate.

Fellows' Syrup does this effectively. It therefore becomes the one most valuable preparation in these conditions.

Suggested dose: One teaspoonful three times a day well mixed with water,

"The other five courses of the series will be given by Dr. McCord on June 26, July 10, July 24, August 7 and August 21, respectively. Definite places have not yet been selected, but will be announced later.

"We feel that Kentucky physicians are extremely fortunate, at this time of economic stress, in having brought to them an unexcelled opportunity for up-to-date postgraduate instruction, without the expense of a trip away from home

"Dr. McCord's lectures are financed by the United States Children's Bureau, and are offered to local medical societies through the Kentucky Medical Association and the State Board of Health."

THE INDIGENT IN MICHIGAN

The Journal of the Michigan State Medical Society for March contains a description of the plan for the care of the indigent in Battle Creek, which is a city of 50,000 population, with 111 doctors, 45 of whom entered into the plan described as follows:

"A meeting of Battle Creek physicians and dentists was called, November 10, 1932, which resulted in the formation of the Battle Creek Academy of Medicine and Dentistry, a non-profit non-Their first undertaking dividend corporation. was to obtain the facts as to the number of cases treated in other years, and the aggregate costs to the county for their medical care. These figures through the free cooperation of county officials, were made available, and were taken as a basis for an estimate for future service. Based upon these findings, a contract was made with the city to furnish medical care, with ordinary medicine and including surgery to the indigent sick in Battle Creek for the year 1933, for the sum of \$12,000, payable in semi-monthly installments of

"The next vital question to settle was the prob lem of determining the economic status and worthiness of the family requiring attention.

"The Academy of Medicine and Dentistry has its own investigating committee, who with an experienced social worker and former county nurse, whom they employ at their own expense, together with the city appointed Director of Relief, serve the interests of both doctors and the city by investigating the worthiness of each case.

"Each member of the Academy would at once render first aid with no question as to forthcoming pay. He at once makes his report on a special notification card, to the Academy headquarters and the visiting nurse, together with the relief director employed by the city, investigate and, if found worthy, the doctor continues to give medi-

(Continued from page 720-adv xii) cal care until the case recovers. If unworthy, the doctor would treat the case as any other private patient. At the end of the month he sends an itemized statement to the Auditing Committee of the Academy This bill for service is rendered at the usual prices for such service in this city. The Auditing Committee discounts the bill 50 per cent, and then at once pays the doctor half of the discounted bill or 25 per cent of the original bill The rest of the account remains unpaid until the end of the year, when any remaining funds available would be pro rated up to the amount of the unpaid balance of each doctor's bill pense of hospitalization, special orthopedic appliauces, insulin, vaccines and a few other specials are not included in this plan, but are specially pro vided for by the city

While the Academy is now in actual operation,

it is yet too soon to say how perfectly it will function. It doubtless has many weaknesses, but it is expected that these will be corrected as soon as they appear The number of cases passed by the investigating committee for medical care during its first month of existence suggests that a hugh epidemic is raging However this apparent rush of business is explainable on the ground that all those registering at the city welfare headquarters are given carte blanche service by the Academy members in case of sickness. After a few months, or possibly not until the end of the year, it will be possible to pass judgment on how well it fulfills its mission Careful records of cases by the Social Worker, and systematic accounting of its funds are being kept by an expert accountant and, as the experiment unfolds, one may hope for a wealth of facts upon which to guide in other experiments of this kind "

PRESIDENT'S MESSAGE IN SOUTH CAROLINA

The April Journal of the South Carolina Medical Association contains the following message from its President, Dr J R Young

"'I shall restore unto you the years the locusts have eaten' This picturesque but heartening prophecy spoken by the prophet Joel in the long ago carries a very pertinent message for these

vears of depression. None will deny that the locusts have subbled away industriously these latter days. Stocks bonds, lands, bank deposits, and what not have been tempting morsels for this rapacious brood of hell?

"A group whose capital investment has been (Continued on page 722-adi xiv)

placed where thieves can not break through and steal has indeed been fortunate during these strepuous days. Doctors compose such a group. Their principal investment is their knowledge and experience. This the locusts may not devour. The members of our profession may have lost certain salted away dividends on their capital, but in the large view these losses are minor and our principal capital investment remains intact. What wiser course could the individual doctor follow during these lean years than to be continually adding to his capital stock? The doctor who fails to take advantage of this patent fact is not wise. Perhaps no method has been found of converting knowledge and experience into clinical wisdom that is superior to the regular habit of active, intelligent participation in county medical society work. The doctor who redeems the time in this way, places himself in a position to have restored unto him the years that the locusts have eaten."

GRADUATE EDUCATION IN FLORIDA

The March issue of the Journal of the Florida Medical Association contains the following editorial on a proposed graduate education course:

"Plans are nearing completion for a post-graduate medical course to be offered to the doctors of the State by the University of Florida Extension Division and sponsored by the Florida Medical Association, according to an announcement made by Dr. Gerry R. Holden, president.

"A committee, appointed by Dr. Holden, composed of Dr. T. Z. Cason, Jacksonville, chairman; Dr. G. C. Tillman, Gainesville, and Dr. T. H. Bates, Lake City, has been at work on the arrangements for the project during the past several weeks, in collaboration with Dean B. C. Rile; of the General Extension Division and Mr. W. K. Mitchell, Secretary of Institutes and Short Course Bureau, at the University.

"As outlined by the committee, the course will consume six days, June 19th to 24th. It will include six lectures each on surgery, obstetrics, pediatrics, and medicine, and two each on eye, ear, nose and throat, dermatology, laborator, work, and x-ray. All subjects will be considered from the standpoint of the general practitioner and not from that of the specialist in these various subjects.

"The lectures in the major courses will be given by full professors from various medical schools Dr. Wayne Babcock, Profesor of Surgery in Temple University of Philadelphia, has kindly consented to give the course in surgery.

"Further information concerning this cours' will be sent out soon by the Extension Division of the University of Florida."

ACADEMIC AND INDUSTRIAL RESEARCH IN THE FIELD OF THERAPEUTICS By SIR HENRY H. DALE, M.D., LONDON, ENGLAND

An Address delivered at the opening ceremony of the Research Laboratories of Merck & Company, Inc., Rahway, New Jersey, on April 25, 1933, by the Director of the National Institute for Medical Research, London, England, and Secretary of the Royal Society of London.

TE have today the privilege of assisting at the formal inauguration of these Research Laboratories, which the enterprise of a manufacturing house has brought into being. I know that I can speak for all those who are present, in saying to the directors whose enlightened policy has provided these laboratories, and to the distinguished investigators who will use them, that we wish them all the success which they desire and deserve. And in wishing them success. I have in mind not merely such as will directly increase the efficiency and extend the scope of the industrial enterprise with which these laboratories are associated, though that we may wish them without reserve; but we may also wish them a wider and more enduring success, in adding to the sum of life-saving knowledge, for the benefit of all mankind.

Research Industrially and Scientifically.-The word "research" in relation to industry has been made to do duty over a wide range of meanings. You would probably find some manufacturers who apply the term to the mere experimental control of the details of an unprogressive technical routine, or of the quality of the materials used in it. At the other end of the scale, this great country, in particular, can show conspicuous examples of the far-seeing policy of great industrial enterprises, in providing opportunity for men of world-wide fame in science to follow freely the lead of their own original genius, without any immediate reference to the production of remuncrative inventions. Results of the greatest theoretical importance to science have thus been obtained, which any University might be proud to claim as the product of its laboratories of pure research; but in some cases, at least, they have been obtained under conditions which only the technical resources of great industry could provide. I do not think that we can have any doubt that, by such a policy, industry will not only render a proper service to the wider interests of the Community from which it draws its support, but will also act in the essential interests of its own

success and development. And it will do so, I think, not merely because some of the most important inventions, leading to really new lines of practical development, do in fact arise as incidental results of fundamental researches having no such practical aim; but also because the progress of such free scientific enquiry in any community creates the atmosphere of mental enterprise and the fount of ideas, which enable practical invention to thrive and to come to fruition.

Industry and the University.-There may be some who will see a danger here, fearing lest the opportunities offered by the research service of industry may come to make too large a draft upon the highest grade of scientific ability, so that the Universities may be unable to make good their primary claim upon it, for the training and inspiration of the following generations. danger is not one which could be treated lightly if there were any good reason to fear its development. For the scientific future of any country, in industry as well as in the academic sphere, must depend on the quality of the recruits which the Universities can furnish; and that quality will be determined, not only by the effectiveness and the attractive influence of the formal teaching which they provide, but even more by the opportunity which they afford to their best students, of a living contact with the finest type of ability and achievement in research. If such a danger really existed, we could hardly put the responsi-bility for it only on industry. The great institutions, supported by private munificence or by public funds, and offering, to men selected for their achievement or promise as investigators, an opportunity to give the whole of their thoughts and energies to research, must share any responsibility of that kind,

This country, through the imparalleled and enlightened generosity of its leaders of industry and finance, has led the world in this relatively new development of the endowment of research for its own sake. I myself have the honor now

N. Y. State J. M June 15, 1933

to be associated with an Institute thus devoted entirely to medical research, with no formal academic contacts, supported from the public funds by the British Government. Earlier, after a relatively short academic experience, I had charge, for ten of my most active years as a scientific worker, of laboratories also concerned with various aspects of medical research—physiology, pharmacology, immunology, serology—and supported by the head of a great British pharmaceutical firm, Sir Henry Wellcome, who had migrated from your country to mine at an early stage of his career.

I allow myself the apparent egotism of these personal details only to make it clear that I have had the opportunity of viewing, from more than one angle, this problem of the relation between research in the Universities, in endowed and public institutes, and in laboratories supported by Industry. And, so far as this experience has enabled me to form a judgment, I do not believe that there is any real or permanent danger of the Universities losing, to whole-time research in endowed institutions or in laboratories associated with Industry, the particular kind of scientific leadership and power of inspiration, which, in the interests of all kinds of scientific activity, it is essential that they should retain.

Careers in Industrial Research.—So far as I can judge, I believe that, in general, this relatively new growth of whole-time research as a career is already effective, and is likely to become more so, in the reverse direction. In this, as in other spheres of human activity, supply must be largely determined by demand. The Universities, in the nature of things, can offer only a limited number of major opportunities in science to their ablest and most enterprising students; and the more numerous the extra-academic opportunities for careers of distinction and of service to the community in research, the more readily will able men be willing to try their ability as investigators, before embarking on careers of professional practice or business; and the wider should be the field thus made available to the Universities, in choosing the men they wish to retain and to promote. I do not think, then, that there is any real danger in that direction. Such difficulties as may arise, to hamper the development of the best and most helpful relationship between research in the Universities and in the laboratories associated with Industry, must come from causes of a different kind.

In the field of medical science, which is that of my own direct experience, I am inclined to doubt whether the ideal relationship has yet been everywhere established, between research in the Universities and the hospitals on the one hand, and that associated with the pharmaceutical industry on the other. The finding and acceptance of a proper relationship, however, is vital to the

progress of both alike, and to their union in an ordered advance, along the common front of medical science and its applications. It is a matter of special importance to an institution such as this, which starts today on its career, with the good wishes and the confident hope of us all. I hope, therefore, that I may be allowed to put briefly before you a few ideas as to the special kind of service which an organization such as this may render to medical science, and as to some of the difficulties which it may have to face.

Altruism of Medical Research.—Let us recognize, in the first place, that investigation in that group of sciences which contribute to medicine entails certain special obligations. The practitioners of medicine are bound, by a tradition of long and honorable history, to place any new knowledge, gained in the practice of their art, freely at the disposal of their professional brethren, without any concealment or any attempt to restrict its use for private advantage. This tradition has no connection with any formal code of professional etiquette governing medical practice. Its basis, I think, is a recognition of an essential condition for the advance of medical science; and in recent years, as such advances have come in increasing measure from the research laboratories, the workers in these, whether medically qualified or not, have in general shown themselves eager to embrace this great medical tradition, and to accept this freedom of the great medical brotherhood. Without committing ourselves too hastily in advance to the details of its application over the whole field of enterprise, I think we must accept this tradition as embodying a true ideal, and one which we cannot afford to lose or to see obscured. For medical research differs from that in other fields in this respect, that its ultimate aim is the provision of knowledge which will find its application in the relief, the cure, or the prevention of human sickness and suffering.

Coordination of Medical Research with Clinical Practice.—Further, while all medical research, however remote from any immediate thought of such application, preserves this ultimate aim, no practical development of the results of medical research can be made, no therapeutic invention can be completed, without a full and frank cooperation with those engaged in clinical practice. Those who are engaged in the task, vitally important to the progress of medical science and practice, of translating the new knowledge of natural laws and principles into terms of practical therapeutics, as the workers in these laboratories will be, require the fullest confidence and cooperation of those, on the one hand, who are freely exploring new avenues of knowledge, without an immediately practical objective, and those, on the other hand, who are directly responsible for the care and the treatment of the sick. And

in order that this frank and full cooperation and confidence may be established, between all those engaged in furthering medical discovery and its application at these different stages, they will need to convince one another that they are bound together in a common cause, and by loyalty to a common tradition.

Trade Interests.—I think that we must frankly face the fact that those whose contribution to this common end is made by research in laboratories such as these, may find a special difficulty in carrying that conviction. These laboratories have been founded by Industry, and their maintenance and progressive opportunity of service to medical science will depend on the extent to which Industry receives the proper reward of its enterprise. I have no fear that the directorate responsible for these laboratories will reckon that reward by any narrow calculation, based merely on returns from directly remunerative invention. But you men of science, who have accepted the opportunity which these laboratories offer, will probably find some among your academic or clinical colleagues, who will be ready to assume that your researches, henceforward, will be directed merely to the promotion of some trade interest, to securing some advantage to the manufacturing house supporting you over its competitors, and not to the advancement of the common cause of medical science. I say that you will probably find some ready to take this attitude, and to regard you as engaged in, at best, an inferior order of medical research; but it may be that I am wrong, and I hope that I am. I was speaking from the analogy, perhaps a misleading one, of my own experience in another country, and now nearly 30 years ago. I suspect, however, that human nature and academic traditions do not exhibit any fundamental differences over those parts of the world where our common language is spoken, and that they do not change completely in the course of thirty years. If there is anything in my suspicion, it will be your task, as it was mine, to show these colleagues that they have been wrong in their assumptions; that work in these laboratories supported by industrial enterprise, though differing from theirs, perhaps, in the nature of its immediate objective, can be as genuinely inspired by the ideals of the advancement of medical science, and of service to suffering humanity; and that even in researches undertaken in the interests of some immediately practical development, the alert investigator, given such freedom as you will surely have here, will find the opportunity for making additions to the common fund of scientific knowledge, which may be as fundamentally important as those which come from the academic laboratories. They have had examples before them, indeed, for many years, from other laboratories established and maintained by great pharmaceutical houses in this country.

It must surely be generally recognized that some of the great advances in medical knowledge, which have in recent years come from American Universities, have been made possible by the cooperation which only industrially supported research could give. But prejudice dies hard, especially when it has its roots in a tradition which we all acknowledge and respect; and I suspect that you who are to work here will find that there is, for yourselves and your colleagues in other similar institutions, something yet to be won, of the full confidence and cooperation which you need from the academic investigators, and which they as certainly need from you. You will win it, when they see that your work differs from theirs not so much in its quality or its ultimate aim, as in the nature of the incentive, and in the kind of opportunity offered by the conditions under which it is done.

Palents.—There is one matter affecting the question of loyalty to a common medical tradition, which I must mention more explicitly, if only to free myself from the suspicion of shirking a difficulty. I refer to the question of patents for inventions having therapeutic value. I shall make no attempt to conceal my own wish that we could do without them. I am convinced that a general recognition of their use by research workers in the medical field would be unfavorable to open confidence and to the free interchange of experience and materials among such workers, including those whose part in a common investigation is concerned with the human patient. The whole basis of such cooperative work would be endangered by any suspicion that it was being used for the enrichment of some individual or institution, and not for the advancement of medical science for the common benefit.

That being said, I should make it clear that I am not among those who condemn the use of patents in medicine with a kind of dogmatic fervour and without reference to its object and its effect. The object of any patent law is to further the progress of science and its applications, by stimulating invention and by providing the conditions which will make its results available to all who need to use them.

I believe that a general use of patents in all parts of the field of therapeutic research and by investigators in all kinds of institutions would definitely hinder, rather than promote, such progress. That belief, however, does not entitle me to suggest that the protection by patent of any kind of therapeutic invention, under any conditions, and in any country, must of necessity have that detrimental effect.

So far as I can judge the situation, the danger of its seems to me to be greatest in connection with discoveries relating to remedies of the biological type, for which the practical application is apt to present itself as a stage in the general ad-

vance of knowledge, to which many, in different institutions and countries, have made essential contributions. I believe that there is a definite danger here from the difficulty of distinguishing between scientific discovery and practical invention, and from the temptation to use the opportunity which a patent affords, not only to endow a particular institution in which a practical development happened to begin, but also to dictate to the whole world an orthodoxy in its application, and thereby to restrict the freedom of further advance. Frankly, I am inclined to regard the medical patent as a peculiarly dangerous weapon when it is wielded by the good intentions of the academic amateur.

On the other hand, I do not see the same danger in the use of patents for inventions related to really new substances of therapeutic value produced by chemical synthesis. I cannot ignore the argument that an immediate and complete freedom to all the world for the manufacture and sale of such a substance might have the result of its not being produced at all, because nobody could justify the expenditure necessary to organize its efficient production and to make its value known to those who could use it. I think it could be urged that, under the conditions of modern pharmaceutical industry, in some countries, a patent for a definite invention of this kind may be used in accordance with the very purpose of medical tradition, to make the new knowledge available to all who need to use it. I think that it can also be urged that such a policy may enable an industry to support research leading to further and more important inventions.

Without such incentive and guarantee it is ardly likely, I think, that the great pharmaceucal industry of Germany could have embarked n a policy which, after many years, has led to the production of substances representing the first ear advance in the treatment of malaria along ew lines since the Jesuit Fathers brought Cinhona bark from Peru in the 17th Century; or not the pharmaceutical industry of this and other puntries would have enriched the resources of the reduce with all the new general and local naesthetics which now help to reduce the sum of uman pain.

If the industry of any country tells me that it in promote research and apply its results in this ynthetic field of therapeutic invention only by ie use of patents, I cannot presume to contest ie statement. But I am certain that patents in ie medical field will do no service, even to industy, unless they are so used that they serve also ie great medical tradition, so that industry wins not retains the confidence of the academic labratories and the clinics. No invention in the iedical field can be completed or brought to use ithout the cooperation of the physician and his atients. I believe that such cooperation will be

readily and properly given so long as it is clear that the aim of industrial research is the real increase of knowledge for the ultimate benefit of mankind, and not the promotion of some narrow commercial aim.

Coordination of Academic with Industrial Laboratories.—The idea of cooperation involves some differentiation of function. It would not be in the general interest of science that the academic institutions and laboratories such as these should be following exactly similar lines of investigation, with the same kind of immediate objective. Broadly, we may distinguish their respective functions, I think, by saying that the primary task of those academic laboratories, which are concerned with the ultimate advancement of therapeutics, is the increase of our fundamental knowledge of the problems involved, without any immediate or insistent thought of its practical application. The function of science in the Universities seems to me to be well expressed in the old formula, which, since its foundation in the seventeenth century, has defined the purpose of the Royal Society of London—"the improvement of natural knowledge by means of experiment." That tradition has not needed any artificial importation into the Universities of this country. One of the first and greatest of American citizens, Benjamin Franklin, was himself a distinguished Fellow of the Royal Society.

Your primary task in industrial laboratories, on the other hand, will be to find applications for the laws governing therapeutic action, as fundamental inquiry reveals them; and to translate them into the practical terms of remedies ready for the treatment of the sick.

Practical Applications of Research.—Broadly, I think, this differentiation can be made, and 1 believe it to be important that it should be kept steadily in view. On the other hand, it is natural and proper that, from time to time, these functions should largely overlap. The academic investigator must certainly not be inhibited or called off from his quest, if its natural line of development should lead him to a discovery which is directly applicable to the prevention or treatment of disease. On the contrary, it is right that he should be the more encouraged to pursue his investigation, by the thought of its promise of immediate benefit to mankind. I suppose that we shall agree that the discovery, in the past century, which had the most revolutionary and transforming effect on medical science and practice was that of micro-organisms as the cause of infective diseases; and its real starting point was the interest, awakened in the mind of a man of genius, Louis Pasteur, by the relation between the optical rotations of the different tartaric acids and the asymmetry of their crystals. He followed the clue through the differential fermentative action of moulds and of yeasts, to open a new world to investigation, in the bacterial origin of putrefaction and of many diseases. But, out of an unbounded admiration for that great man and for his wonderful gift to mankind, I am sometimes tempted to wonder whether that gift might not have been even greater, and in some of its phases more permanent, if the clamour for practical application had not led him, in later years, so far into the unfamiliar field of therapeutics, and away from his more fundamental enquiries.

When Michael Faraday, patiently seeking the improvement of natural knowledge, with an inspired curiosity, discovered the phenomenon of electromagnetic induction, he probably had little thought that it would find any practical application; if he had had any provision of the kind of civilization which, a hundred years later, would have arisen on his discovery, the thought would probably have appalled him. It will surely happen in the future, as in the past, that free and fundamental researches will often lead to the most important practical discoveries; and we need not grudge his good fortune to the academic investigator whose work has such a result. I do think, however, that there is a definite danger lest he should be diverted by it from his proper task of further free enquiry, and should devote his interest to the practical development and application of a discovery already made, which, in many The coneases, he had better leave to others. eentration of popular enthusiasm, on discoveries which are immediately applicable in therapeutics, is natural and intelligible. We need have no fear of its effect, provided that a proper balance of recognition is preserved within the Universities themselves, between the achievement of a praetical success, and the fundamental advancement of knowledge.

Financing Academic Research.-I have no right, and no desire, to criticize here a particular line of policy, which some of the Universities of the North American continent have adopted in recent years, in order to secure to themselves funds for the endowment of further research, from the proceeds of practically useful medical discoveries which have come from their respective laboratories. It is for them to judge their needs, and the proper way to meet them. I mention the matter, not from any desire to make or to imply a criticism of action already taken, but because of its direct bearing on a view which I desire to emphasize, namely, that the primary and special function of research in the Universities is to build the main fabric of knowledge by free and untrammelled inquiry, and to be concerned with the practical uses of it, only as these arise in the course of a natural development. I suggest that we should watch carefully the effect of any line of action, which might lead the scientific departments of the Universities to give encouragement and promotion to the practical inventor, at the expense of withholding it from a potential Michael Faraday or Willard Gibbs. If that should happen, there would be a real danger of the University departments neglecting their own proper part in the cooperative scheme, and encroaching on that more proper to the laboratories supported by Industry.

Altrustic Research in Industry.- I have suggested, as the primary concern of the laboratories supported by Industry, the development to a practical outcome of the fundamental discoveries which the academic and endowed institutions may be expected, in the main, to furnish. But just as the academic worker ought not to be restrained from following freely the line of his enquiry, because it happens to lead to a practical application, the investigator in an industrially supported laboratory ought to have a large freedom to follow a clue to new knowledge of a fundamental kind, if it presents itself in the course of his practical investigations. Indeed, I think it is probably of great advantage to an industrial laboratory that its staff should have always in hand a substantial body of investigation having no direct relation to any praetical development,

My own personal experience, if you will pardon a further reference to it, perhaps influences my views unduly. If the head of a great pharmacentical house, who gave me my first real opportunity as an independent investigator, had been inclined to judge me by my output of therapeutic novelties directly remunerative to his firm, I think he must have concluded that I was a very unprofitable investment. If he did so, he never let me suspect it; on the contrary, I received a steady encouragement to follow, with my colleagues, the natural lead of the problems which our initially practical investigations had presented. And I believe that such a policy is undoubtedly the right one.

If necessity is the mother of invention, the spirit of free investigation is most certainly its father. The men who work here will need it, to preserve their active interest in what is happening in the larger world of science, and to maintain their contacts with men of like interests in the academic world.

In a very large proportion of cases, when we come to look at the results, it will be difficult to say whether a particular discovery would come more appropriately from an academic or from an industrial laboratory. Permit me to illustrate the difficulty by an example which has some personal interest for me, as well as for these laboratories.

Many years ago my friend, Dr. Reid Hunt, now Profesor in the Harvard Medical School, thought that he detected the presence, in an animal organ, of some unstable derivative of choline, of greater physiological activity than that substance. An examination of a series of artificial derivatives, with Dr. Taveau, led him to the dis-

covery, in acetylcholine, of a substance having at least one thousand times the activity of the parent base.

Some five years later, in the Wellcome Laboratories, I was still following up certain lines of enquiry on the pharmacology of ergot, which had been suggested to me as a subject when I entered that service. A remarkable type of activity showed itself in certain peculiar ergot extracts, and co-operative work with my colleague, Dr. Ewins, led to the isolation of the substance responsible for it, which proved to be acetylcholine. Acetylcholine thus passed from the class of synthetic curiosities into that of natural substances, and a fuller study of its action showed a remarkable relation between its effects on different organs and those produced by parasympathetic This work, in an industrially supported laboratory, had brought us no nearer to practical therapeutics than Professor Reid Hunt's original discovery had done; but it arose from a chance observation, for which only the industrial connection could have provided the opportunity, and of which we were able to take advantage through our association with large-scale work.

After another interval, created by the war, the next step was taken in an academic laboratory, when Professor Loewi, in Graz, showed that stimulation of the vagus nerve produces its effect on the frog's heart by releasing something remarkably similar to acetylcholine in its properties; but the quantities were far too small for direct identification. After another interval of years, now in an institute supported by the public funds, another chance observation enabled Dr. Dudley and myself actually to isolate acetylcholine from an animal organ, in quantity sufficient for complete identification. So that now we had evidence that this substance, the most powerful dilator of the arteries of which we have any knowledge, actually occurs as a natural constituent of the body, and almost certainly intervenes in the natural control of its functions. But still its instability, and the consequent evanescent nature of its action, while fitting it supremely for such a natural function, made it of very doubtful value for artificial application in therapeutics.

And so the scene shifts again to the industrially-supported laboratories, and the systematic search begins for allied esters of choline, with a similar but more persistent action. And already there is news of the discovery of several; of one from the laboratories of the ancestral house of Merck in Germany; of another, apparently of real therapeutic promise, from the research laboratories of this younger house of Merck, for the inauguration of which in their new form we have been invited here today. The pharmacological properties of this new substance, however, were first made clear by Simonart, working under academic conditions, in the laboratories of my

friend, and for a time my close comrade in research, Professor A. N. Richards of Philadelphia. I congratulate these laboratories on securing the cooperation and advice of Professor Richards in relation to their activities in fundamental research. The association, as you will see, has a double interest for me; but I take almost as much in tracing the successive stages of this investigation, from the academic to the industrial laboratories and back again, and in finding myself unable to suggest that the nature of the researches at any one stage was specially suited to an academic institution, and at another more appropriate to the function of an industrial laboratory.

Temperament of Research Workers.—I have spoken of the broad differentiation of aim and of function between academic and industrial research, and of the different types of ability and of temperament suited to each. There are men, indeed, of whom we could say with confidence, that the associations of academic life are necessary for their happiness and their efficiency in research; and there are others of whom we could say with equal certainty that their best work would be done under such conditions as these laboratories provide. I believe, however, that the men so easily classified are realtively few, and that for a large majority the choice will be determined by the accident of opportunity, rather than by aptitude. For some of this majority, I suspect that the best conditions for the full development and maintenance of their powers of serving science, might be provided by a successive or an alternating experience of the conditions of academic and of industrial research. The investigator who has been digging himself to a standstill in an academic groove, might find a new mobility in the less conventional surroundings of an industrial laboratory; while his colleague whose inventive energies have grown stale, from too long contact with a variety of practical problems, might find them refreshed and renewed by migrating for a period to the calmer atmosphere of fundamental research. I believe, then, that a freer interchange of suitable personnel, if it were possible, between the academic laboratories and those supported by industry, might have an invigorating influence on both; but I speak of ideals, without knowledge of practical possibilities. I am sure that even a short experience of the kind of opportunity that these laboratories will afford, would make some of your academic colleagues envy the elasticity of organization, the adaptability of equipment, and readiness of expansion to a large scale of working which the industrial association can give.

Absence of Restrictions.—There are several advantages which you will have here over some institutions supported by memorial endowments. I am sure that this country must have had examples of a type of large-hearted testator or pious

founder, familiar to us in England. He rightly believes that he can create the most worthy memorial to himself or to those dear to him by the endowment of medical research; but too often he wrongly believes that his generous impulse brings with it a scientific vision and a proplictic wisdom, entitling him to restrict, for all time, the application of his benefaction to research on some particular problem in medicine, which has enlisted his personal sympathies or stimulated his imagination. You who work here will be free to choose your problems, according to the needs of the time and the promise of advance offered by current progress in science; you will be able to give intensive cultivation to the fertile areas, to raise the erops which are likely to give good yield, and out in the sickle where the harvest stands ripe for gathering. You will have the great advantage that your buildings can be designed and equipped, with the sole aim of making the most efficient provision for the work which you have in hand or in near prospect. You begin with an equipment perfect for your present needs, and will be able to expand it as your programme and your staff expand. I can hardly resist a feeling of envy at the opportunity which Dr. Major, Dr.

Molitor, Dr. Engels and their co-workers will have, to concentrate their thoughts on their researches, without distraction by duties of administration or teaching, in laboratories designed so admirably for the needs of research, and so readily adaptable to changing requirements.

Cooperation of Industry and Universities.— Whole-time research, however, whether in an endowed or an industrial laboratory, has its own special anxieties and psychological needs. search workers in an institution such as this can only give of their best, if they can escape from any feeling of isolation from the general scientific community, and can feel an assurance that their work is making an essential contribution to the general advance of medical science and practice. They will need, and I am confident that they will have, all the encouragement and friendly cooperation which their scientific colleagues in the academic laboratories and the clinical centres can give them. We wish them all success, and we eongratulate the President, Mr. Merck, and all who have been associated with him, on an enterprise which we now launch, with high hopes, on a career of service to science, and to the Industry which supports it.

THE SIGNIFICANCE AND DETECTION OF TUBERCULOSIS IN SCHOOL CHILDREN

By WILLIAM J. RYAN, M.D., SUMMIT PARK SANATORIUM, POMONA, N. Y. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., on May 25, 1932

THOSE of us who are familiar with the tuberculosis situation in our sanatoria realize that
beds are occupied by too large a percentage
of patients with advanced tuberculosis. The results of the Early Diagnosis Campaign, which has
been carried on intensely during the past few
years, have been disappointing in detecting early
tuberculosis.

While the mortality curve has shown a marked decline during the past 25 years, the decline during the age-period of 15 to 24 years has not been proportionate. It is now generally recognized that tuberculosis in the teens and early twenties is usually a manifestation of childhood infection which has been undiscovered and untreated, although there are some who now believe that tuberculosis occurring in the young adult is often the result of a primary adult infection.

We believe that most tuberculosis in its early stage cannot be recognized until those under 30 years of age will have their chests x-rayed periodically; but the public has not as yet been educated to this point. An approach to this problem, however, is being made by the examination of students in elementary and high schools.

This paper deals with the results obtained from a study of 1,885 school children in Rockland

County, New York, by means of the tuberculin test, and a study of the x-ray film of the reactors for the purpose of discovering early tuberculous lesions in the lungs.

PATHOLOGY OF CHILDHOOD TUBERCULOSIS

Since the pathology of childhood tuberculosis differs in character from that of the adult type, a brief review of this subject will be given.

Our present conception of tuberculous infection in childhood is briefly as follows: The aerogenous channel as the entry of tubercle bacilli into the lungs is now generally accepted as the most frequent portal. Tubercle bacilli, when inhaled, lodge in the terminal bronchioles usually near the periphery of the lung, and a localized, inflammatory exudate is set up which, if recognized at the time of infection, would resemble a bronchopneumonia. In infants the disease occasionally progresses to massive consolidation and death. Usually, however, this condition passes undetected during the acute phase, to at least a temporary recovery.

From this primary focus tubercle, bacilli are carried by the lymphatics to the lymph nodes at the roots of the lungs, and there set up seemadary foci of infection. In the area of the lung where the tubercle bacilli were implanted, the cellular elements may be completely absorbed, leaving no evidence of the infection, although a small area of caseation is the rule and this is followed by a gradual deposit of lime salts, leaving one or more calcified nodules usually in a lower lobe. calcification can result only from the deposit of mineral elements in a caseated tuberculous focus; and when this pathological picture is present, the infection has been unusually severe. A similar pathological picture has developed in the tracheobronchial or mediastinal glands of the lung infected. The glands become enlarged and caseous, followed by calcified deposits, and are more frequently detected on the film than the primary lung focus, although the calcified lymph nodes may be present, but obscured on the film by bony or other

Therefore, tuberculosis of the tracheobronchial lymph nodes is always preceded by a primary pulmonary focus which may or may not be visible on the x-ray. This pathological condition is the result of a tuberculous infection in a previously uninfected child, and is spoken of as the "primary complex," first described by Parot in 1876, and again confirmed by Kuss in 1898, and Albrecht in 1907, and amply verified by Ghon in his classical work published in 1916.

After careful study of abundant material, pathologists are unanimous in their opinion that primary infection of the tracheobronchial lymph glands does not occur. The following is a statement from Ghon: "The investigations of Kuss. Albrecht, and my own have proved almost without exception that a focus can be found in the lungs bearing distinct relations to the adjacent altered lymph nodes, and which is often small but can be detected by appropriate post mortem methods." Of Ghon's 184 cases with tuberculosis of the tracheobronchial lymph nodes, 174 or 95% showed a primary lung focus.

THE INCIDENCE OF INFECTION

It is now generally accepted that the tuberculin test is almost a specific in determining the presence or absence of tuberculous infection. There is also evidence to indicate that there is a relation of the intensity of the tuberculin reaction to the gravity of the lesion, but not necessarily to its size. However, a reaction to tuberculin does not indicate clinical disease. The number of positive reactors varies according to the method of testing used (whether Von Pirquet or Manteaux), the dosage of tuberculin, the different ages, and different communities; it being larger in the more densely populated centers with poor home surroundings.

In a study of 50,000 school children by Chadwick in the State of Massachusetts, using the Von Pirquet test, he found that there was an increase

of infection from 20 per cent at the age of 5 years to 35 per cent at the age of 15. He estimated the state-wide average to be 18 to 20 per cent. Chadwick found that 80 per cent of children under 5 years of age are infected when they are living in families where an open case of tuberculosis exists, while in non-tuberculous families but 20 per cent of the children of the same age are infected.

In 1924 Slater made a study in rural Minnesota by means of the Von Pirquet test and found that 10 per cent reactors.

In the Philadelphia schools 37.7 per cent were positive at 5 years, and the percentage increased

to 90.2 per cent at the age of 18 years.

In our study of 1,885 students, nearly all in the 7th and 8th grades and high schools, there were 52.14 per cent who reacted. This survey was made in the high schools of three villages, each with a population of about 5,000, and two smaller villages of less than 1,000 each, and in some rural grade schools of Rockland County, New York, which is located in the metropolitan area about 30 miles from New York City.

· PURPOSE OF STUDY

1. To detect cases of manifest active tuberculosis, particularly of the adult type and promptly place them under the proper treatment, as well as to break the contact with other children if any such cases had positive sputum.

2. The discovery of any infected children with latent disease who might profitably receive treatment that would prevent the further development

of tuberculosis.

3. After the detection of tuberculosis in the child, latent or otherwise, to investigate other members of the family for the source of infection, and the examination of the remaining children in the home.

PRELIMINARY PROCEDURES

The greatest obstacle in carrying out this survey was to obtain from the parents a written consent for the examination, especially for the tuberculin test. But little objection was made to x-raying the children. A very thorough and carefully laid plan for education and arousing the enthusiasm of the parents and school authorities was carried out.

Approval of Board of Education.—Our first step in the village, where we planned the survey, was to ask the Board of Education for the opportunity to explain to them the importance and purpose of the work. The medical inspector, nurse, and principal were invited to attend this meeting. We have always found that the school board has lent its enthusiastic support.

Mass Meeting for the General Public.—An evening mass meeting for the parents and general public was then held. This was usually conducted by the Parent-Teachers' association and

given wide publicity in the schools and press, during the two weeks preceding the meeting when emphasis was placed on the importance of safeguarding the children's health, but stress on tuberculosis was purposely omitted.

The members of the board of education, the school principal, school nurse, and teachers were urged to be present at this general meeting. A special effort was made to have all the local physicians attend, since the cooperation of the family doctor is most important for the success of this work.

A motion picture dealing with tuberculosis in general was first on the program. The principal speakers at this meeting were physicians who had a standing in the field of tuberculosis, including a representative specialist from the State Department of Health or other official agency who has proven of great value in supplementing the talk of the principal speaker.

The importance of tuberculosis and its significance in early adult life was especially emphasized in our talks; this was illustrated by x-ray films or lantern slides, with case histories, showing tuberculosis in the lungs and proved most effective. The presenting of one or more high school students who had been or were being treated for tuberculosis has, in our experience, had a marked influence on the audience. They were given the opportunity to speak and their comment on the privileges now given for the detection of early tuberculosis in students and which were not available to themselves was most impressive. physicians present were called upon to express their opinion on the contemplated work and, in our experience, they have invariably approved and encouraged the program.

Distribution of Consent Blanks.—On the day following the meeting a letter explaining the purpose of the examination and a consent blank for the parents' signature is given by the school nurse to each child. About 3 days later a further explanation of the purpose of the examination is made to the students, assembled in the auditorium. Following the discussion, the students are free to ask questions. After the lapse of one week, the homes from which the consent blanks were not returned are visited by the school and tuberculosis nurses when further explanation will result in many more signatures. Our experience has proven that 50 per cent of those who originally failed to sign for the test could be obtained by this follow-up method. Frequently the child does not deliver the letter to the parents and, if they do the parents may be indifferent rather than opposed to the examination. Many of the children themselves may object to the test, but by a personal interview in the school such objection can usually be overcome. Many more children, after they observed that the test proved simple and painless, likewise gave their consent.

It is our belief that consent from 75 per cent of the school population can be obtained if the proper program is carried out. However, the enthusiasm and cooperation of the principal, school nurse, and the teachers has, in our experience, been the greatest factor in the success of the program.

THE TUBERCULIN TEST

The Mantcaux or intracutaneous test was used. The number of reactors is higher, and the administration is more rapid than by the Von Pirquet method. However, there are some communities in which it is difficult to obtain consent for the intracutaneous test, and under such circumstances it has been found advisable to use the older method.

One milligram of old tuberculin (New York State Department of Health Laboratories) was given intracutaneously (Manteaux test) and the reaction read seventy-two hours later. The positive reactors were read +, ++, +\dot++, and ++++, as classified by the Diagnostic Standards of the National Tuberculosis Association.

We tested 1,885 pupils, 1,335 of whom were 7th and 8th grade and high school students; the remaining 549 children were from grade and private schools and averaged under 12 years of age. The total number of reactors was 983 or 52,14 per cent, a rather high percentage as compared with the findings in many other communities. The variable percentage of reactors was interesting. Forty-five per cent of the children in the Suffern school were positive to the test, while the Haverstraw school showed 68 per cent reactors, although the age-group was the same, the villages about equal in size, and but seven miles apart. However, Haverstraw village is more the industrial, living conditions are the less favorable, and tuberculosis is known to be more prevalent there.

X-RAY PROCEDURE AND INTERPRETATION

All reactors were x-rayed. One anteroposterior film was taken with a 10 milliampere, 100 volt, portable x-ray machine and double screens. The distance used was 48 inches, and the time, the only variable factor, was from one-quarter to three-quarters of a second. All cases showing questionable pathology were again x-rayed at the sanatorium with a high-power machine, and given a physical-examination before a final diagnosis and classification were made. There were 211 children who were re-x-rayed, and in addition all these children received a physical examination together with a complete clinical history.

The interpretation and classification of the shadows on the chest film of a child is often a most difficult problem. A final diagnosis of such shadows should be made only by one who has had the experience of studying a very large number

of films, and frequently he must combine the family and personal history, symptoms, and physical examination with the x-ray interpretation before a final decision can be reached.

While the roentgenogram is the best method available at present for the detection of tuberculous lesions in childhood, pathologists have recognized the fact that small foci of consolidated lung tissue, even with caseation, are not always opaque to x-rays. It has also been noted that shadows on the film may suggest advanced calcification, while the autopsy findings demonstrate putty-like caseous material with only uniform deposits of mineral salts as the cause of such shadows; and such material may contain numerous tubercle bacilli.

It is, therefore, dangerous to classify petrified lesions as shown by the x-ray as always completely healed. However, "dense sharply defined opacity," says Opie, "suggests that calcification is advanced, whereas shadows of less density, occurring in small spots, which give a granular appearance to the lesion suggest the early state of calcification." The primary complex of childhood, as evidenced by calcium in the lung parenchyma and lymph nodes, which we so frequently find accompanying active adult tuberculous lesions is, in our opinion, the focus for the recent spread in the majority of cases.

CLASSIFICATION OF FINDINGS

Our classification followed that of the Diagnostic Standards of the National Tuberculosis Association of 1931 which is briefly as follows: 1. Observation Cases. 2. Manifest Disease. 3. Apparently Healed.

- 1. The Observation Cases include:
 - (a) Those in whom the x-ray shadows or symptoms, or both, suggest tuberculosis but which cannot be proven at the time of the examination.
 - (b) Those in whom tuberculosis is definitely present, but the proof of latent or active disease cannot be determined at the time of the examination.
 - (c) Children who had a positive tuberculin and were known to have been exposed to sputum-positive cases, although the x-ray is negative. The later group has materially increased the number of observation cases.
- 2. The Manifest Disease cases includes definite pulmonary or tracheobronchial tuberculosis, or a combination of both, with all the evidence of clinical or roentgenological activity.
- 3. The Apparently Healed cases includes lesions which have all the x-ray evidence of com-

plete fibrosis or complete calcification, and the child is free from clinical symptoms.

The difficulty of all workers to classify uniformly the results based on the above standards is obvious. Many may group the majority of calcified lesions as apparently healed. While others, more conservative, are likely to consider a prolonged period of observation as necessary and carry such patients as suspects.

RESULTS

The percentage of tuberculous lesions found by workers in this field is fairly uniform. Rathbun in a study of 3,678 school children in Chatauqua County, New York, reported an incidence of 3.3 per cent as having tuberculous lesions. Of 11,449 children examined by Chadwick in the State of Massachusetts, 4.8 per cent were found to have tuberculosis of the tracheobronchial lymph nodes. Opie and McPhedran of Philadelphia emphasized the increase of tuberculous lesions in children with the increase of age. They report that at the age of 5 years only one-twentieth of those infected show definable lesions; at 10 years approximately one-ninth; and at 15 years, one-quarter. workers of the Philadelphia group have also found that tuberculous foci occur more often in girls than in boys from 12 to 20 years, the rate being 3.4 per cent for girls, while that for boys in the same age-group is 2.1 per cent.

In a study of 1,000 children, ages 13 and 14 years, from the Bellevue-Yorkville District, New York City, Barnard, Amberson, and Loew report 7 per cent of them as having apparently healed tuberculosis, and 11 per cent as having clinically important lesions.

Our study consisted of 1,885 children in the 7th and 8th grades and high schools of five villages, several small grade schools, and two private schools. No attempt has been made to classify the character or percentage of lung lesions in accordance with the age-groups. The students ranged in age from 12 to 17 years.

In the group termed "dangerous lesions" are included all those classified under manifest disease, and a large percentage of the observation cases, where the tuberculous foci in the lung suggest possible incomplete fibrosis or where the calcification in the nodes indicates that there may be some remaining caseation. Any extensive lesion in the tracheobronchial lymph nodes or lung parenchyma was classified as dangerous.

Tables 1, 2, 3, and 4 show the results found in our study of three distinct school groups:

The total number of children with definite le sions, suspected lesions, or those classified as ob servation cases on account of contact, was 217 or 11 5 per cent Of this number we considered 50 or 27 per cent as having "dangerous lesinis" and

will be closely observed, 25 of whom were considered clinically active

In addition to the examination of school children, 123 teachers were n-rayed, 2 were found to have active disease and in need of treatment, 1 case was classified as minimal quiescent, and 12 showed evidence of apical fibrosis or calicification of a tuberculous character but apparently well healed

We feel that a splendid opportunity is offered by this work for the detection of the source of in fection in the homes. Fifty three families in whom the children had tuberculous infection were studied, 108 members were 1-rayed and given a physical examination, including 42, mothers 29 fathers, and 37 other children not included in the school study. Six cases of unsuspected active pul monary tuberculosis were discovered, 4 mothers, 1 father, and 1 boarder. In our study of the 53 families one or the other parent in 18 of the families was found to have arrested tuberculosis. Of the 37 children, 4 cases of active childhood tuberculosis were detected, 4 cases were classified as observation, and 4 as apparently healed

Further study brought out the following facts in relation to the children with positive findings. One or the other parent or some member of the family of 26 children were known to have died of pulmonary tuberculosis. Sixteen children were known to have been exposed to a parent who had, or now has, active pulmonary tuberculosis but is still living. Twenty two children had one parent in whom an arrested lesion was found, but no past listory of activity could be obtained.

We have come to the conclusion that a child reared in close contact with a person who has been an open case of tuberculosis is potentially tuberculous until proven otherwise

SOME CONCLUSIONS

The secret of the adolescent peak of tubercu losis mortality is probably hidden in the period immediately preceding adolescence

By means of the tuberculin test and 1 ray, grave pulmourry lesions may be discovered in children long before they have produced the destructive stage. Careful supervision and treatment of such lesions will, in many cases prevent the development of adult tuberculosis.

Someone has said "Tuberculosis is the last verse of the song, the first of which was sung to the infinit in the eradle". The truth of this state ment in its entirety remains to be proven but we do believe that childhood infection plays an important part in the epidemiology of tuberculosis. The present method of attack through the school offers encouragement and warrants continued investigation.

TUBERCULIN TESTS IN CHILDREN

Comparative Studies with Different Makes of Tuberculin

By HENRY A. REISMAN, M.D., JAMAICA, N. Y.

From the Chest Clinic, Pediatric Department, New York Post-Graduate Medical School and Hospital, and Columbia University.

TOMPARATIVE studies were made with Koch's old tuberculin prepared in and distributed by the Bureau of Laboratories of the Department of Health, New York City, and that of a well known reliable commercial house whose old tuberculin is highly recommended. Studies were made to ascertain the reliability, potency and dependency of the tuberculin prepared by the Health Department, which we have been using in our Chest Clinic of the Pediatrie Department for the past seven years. It is indeed gratif ying to learn that the tuberculin prepared by the City compares more than favorably with that of one of the best commercial houses. With old tuberculin, as it is prepared today, one does not expect to find the same degree of potency in different lots because of lack of satisfactory standards as to activity and potency.

Robert Koch¹ succeeded in isolating the tubercle bacilli in 1882, definitely establishing it as the etiological factor of the disease. Koch also observed that when the products of the tubercle bacilli were injected into tuberculous animals, there were both local and general reactions. This, he designated as the "Tuberculin Test." It is a tribute to the man whose achievement, the discovery of the tubercle bacilli, and the publication of the "Etiology of Tuberculosis" (the fiftieth anniversary of which recently received world-wide recognition—March 24, 1882-1932), that tuberculin as originally prepared by him remains today praetically unchanged.

To a 5 per cent glycerin broth media, 0.5 per cent sodium chloride and 1 per cent dried peptone were added. The tubercle bacilli were then cultivated at a temperature of 38° C. At the end of six weeks there was a pellicle-like growth. The culture was then filtered, the filtrate heated to kill all living tubercle bacilli and then concentrated to 1/10 its volume making a 50 per cent glycerin solution. It is with this concentrated preparation designated as old tuberculin (Koch's O. T.) that the diagnostic tests are now performed.

Tuberculin as prepared by the Bureau of Laboratories, Department of Health, City of New York, differs only from the original method of Koch in that the culture is first heated to destroy all living tubercle bacilli and then filtered and concentrated; rather than filtering first and then heating the filtrate to destroy any living tubercle bacilli, because of the danger associated with filtering live bacilli.

In 1907 Pirquet² described his cutaneous test. In 1908. Mantoux³ described his intracutaneous method commonly known as the "Mantoux Test,"

which today is the tuberculin test of choice. It is the more delicate, sensitive, and reliable test, and produces a greater number of reactions than the Pirquet (cutaneous) method.⁴ Other tuberculin tests are:

1. Subcutaneous test (Koch).

2. Subcutaneous test Local (Stichreaktion) (Escherich) (Hamburger).

3. Percutaneous (inunction) (Moro).

4. Ophthalmo test (Conjunctival) (Calmette).

Of all the tuberculin tests, the Pirquet² (cutaneous), and the Mantoux³ (intracutaneous), are by far the most reliable and safest; and of the

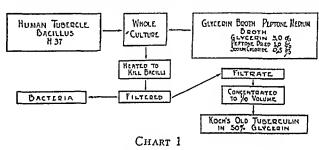

Diagram of the constituents and method of manufacture of old Tuberculin.

two, the Mantoux is the more sensitive and accurate.

There are three distinct phases to the tuberculin reaction:

- (1) Local.
- (2) General.
- (3) Focal
- (1) Local reaction is present at the site of inoculation in sensitive individuals; it consists of swelling, redness, and edema which reaches its height at the end of forty-eight or seventy-two hours, after which time it gradually subsides, undergoing a brownish pigmentation with fine desquamation which may persist for several weeks. Premature pseudo reactions disappear within the first twenty-four hours.
- (2) General reaction may follow the subcutaneous test, which is not commonly used today. Constitutional symptoms usually accompany a positive reaction as a rise in temperature, malaise. nausea, headache, anorexia, and insomnia. A general reaction is to be avoided when doing the tuberculin test in man. Using the intracutaneous method with good technic and the proper dilutions, there need be no fear of any untoward symptoms. The subcutaneous method is the one used in testing cattle. A comparatively large amount

of old tuberculin is injected into the suspected animal subcutaneously. If, within forty-eight hours, there is a sharp rise in temperature, the test is considered positive and the animal tuberculous.

(3) Focal Reaction. In addition to general or constitutional symptoms, in the subcutaneous test, there may be a reaction at the site of the tuberculous focus or lesion. There is increased activity which is manifested by an increase in physical signs. Even though the general reaction be marked, there need not necessarily be a focal reaction.

Over 200 children in the Chest Clinie were simultaneously tested by the intracutaneous method with equal dilutions of tuberculin. For uniformity, the Health Department tuberculin was used on the right forearm and the proprietary tuberculin on the left. The dilutions used were 1-1000 and 1-100 depending upon whether the Mantoux test was previously done, and whether it was positive or negative at either of the dilutions. Both tuberculins were freshly prepared on each day they were used.

In all cases where the Mantoux tests were positive, with but one exception, the City tuberculin gave the more intense reaction. In one instance the reaction with the City tuberculin (1-100) was faintly positive and the proprietary was negative. The majority, however, were 4 plus of the City to 3 plus of the proprietary. The following four cases (Table 1) are representative of the results in comparing the intensity of the reactions of the two tuberculins.

TABLE 1

Four cases illustrating the intensity of the tuberculin reaction.

IS 11 Phlycterular Kerato-	+++	(1-1000)	+
Conjunctivitis; Hilum Tuberculosis W.B. 9 Old Hilum Tuber-	++++	(1-1000)	++
	++++	(1-1000)	+++

In view of the fact that we place a great deal of reliance relative to our diagnosis on the result of the tuberculin test, particularly in children, it is important to know that we are using a potent and reliable tuberculin. Until such time that tuberculin can be properly standardized as to potency, we can expect different lots from different and even the same laboratories to produce reactions of varying intensity, barring, of course, the human factor of faulty technie. When we eonsider the method of preparation of tuberculin, its conglomerate composition with only a quantitative standard, but with no satisfactory qualitative standard to test its activity or potency so as to give all tuberculins equal activity, one must realize the need for such a procedure.

Human Tubercle Bacillus Protein known as

M. A. 100 gives good promise for such a standard. Masueci and McAlpine⁸ isolated the protein M. A. 100 from the filtrate of culture of the human tubercle bacillus H. 37 grown on Longs synthetic enture media. This medium contains no protein, but contains asparagin as a source of organic nitrogen. Hence all proteins present with various other substances not medium constituents in the filtrate must have been synthesized by the tubercle bacillus. Masueci and McAlpine tested this specific protein M. A. 100 in tuberculous lumans and guinea pigs. It gave a typical skin reaction as with Koch's O. T. In humans the dosage necessary to give a reaction was as low as

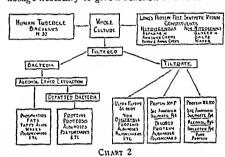

Diagram of the constituents and method of manufacture of Human Tubercle Bacillus Protein M. A. 100

.00005 mgm. In comparison with old tuberculin and Siebert's ultrafiltration method, it was found to be relatively less toxic. W. C. White and J. Burns Amberson are undertaking a elinical study of M. A. 100 under the auspices of the National Tuberculosis and Health Association, through its affiliated associations. Funk and Huntoon investigated the skin sensitivity of man to this partieular human tubercle bacillus protein M. A. 100 when the protein is introduced intradermally as in the intradermal tuberculin test. To control the observations, intradermal tests were made simultaneously with a standard tuberculin O. T. eomparable and safe dosage was established for tuberculin O. T. .00001 c.e. and .0005 mgm. of protein. They found (1) that the human tubercle bacillus protein when injected intradermally elicits in the majority of adults, a skin reaction reaching its height in twenty-four to forty-eight hours, and indistinguishable from that produced by old tuberculin, but apt to be less intense in color and edema; (2) that the skin reaction with M. A. 100 occurs in a slightly greater incidence than that produced by old tuberculin:

TABLE 2
Tests in two groups of cases
Protein M.A. 100, Tuberculin O.T.,
% Positive % Positive % Positive % Positive % 91.2%

81% 71.5%

(3) That in tuberculous individuals and animals the protein is as specific as tuberculin (O. T.) and (4) that disagreeable and dangerous reactions are less apt to occur. In the report of Dr. W. H. Morris¹⁰ to the Research Committee of the National Tuberculosis and Health Association on Protein 304F used as intracutaneous diagnostic skin test, he stated that the 304F protein reactions do not persist as long and are of less. intensity than Tuberculin (O. T.). It is obvious that if the Protein M. A. 100 proves to be as specific as old tuberculin from a diagnostic standpoint, it will be far more preferable to the latter, not only because it is less toxic, but because it is a pure substance which readily lends itself towards standardization as compared to the complex composition of tuberculin (O. T.).

The specificity of the tuberculin test today is undoubted. The younger the child, the more significant its reaction. So much importance is placed upon a positive tuberculin test that, given a young child about three or less suffering from a fever of unknown origin, giving a positive tuberculin test, it is accepted as strong evidence in favor of some form of active tuberculosis. persistent negative tuberculin test rules out a tuberculous infection. However, under certain conditions, the tuberculin test may be negative in spite of a tuberculous focus, as in the following five conditions:

Incubation period:

From the time the child or individual becomes infected to the time he develops a sensitivity and reacts to tuberculin, is called "the incubation period." In the guinea pig, it is approximately eleven days; in man it may be any time up to approximately three months.

- Acute advanced Tuberculous infection with marked constitutional symptoms such as:
 - (a) Acute miliary tuberculosis.

(b) Tuberculous meningitis.

(c) Advanced pulmonary tuberculosis.

A negative tuberculin test in the presence of an acute advanced tuberculous infection indicates a very grave prognosis.

- During certain acute infectious diseases, 5 such
 - (a) Measles.
 - (b) Scarlet fever.(c) Diphtheria.

(d) Others as pneumonia, influenza, erysipelas, and typhoid, to a lesser degree.

According to Abt⁵ 100 per cent of all cases of measles will give a negative tuberculin test. This, however, has not been my experience. In a small group of case's during measles, which Dr. Caldwell and mysel's have observed, 25 per cent gave a positive tuberc'ulin test, and one child had defi-

nite active tuberculosis. Although there are many instances where the infection has caused the tuberculin test to be negative, if one suspects a tuberculous focus, it is advisable to repeat the Mantoux two or three months later, at which time there should be no interference with the test. In order to avoid a general reaction, it is advisable to first repeat the Mantoux with the weaker dilution, and then, if negative, to use the more concentrated dilution. The fact that any were positive during measles is obvious proof that not all children with measles give a negative tuberculin test. Tuberculin Therapy:

During the course of tuberculin therapy, the tuberculin test may become negative. The test is made negative merely from the standpoint of desensitization to a particular dilution. I found that when a Mantoux was repeated with a more concentrated dilution, the reaction was positive. It is advisable, in repeating a Mantoux, to wait at least an interval of one week instead of two or three days, and to increase the dose from .1 mg. to 1. mg. instead of the intermediate .5 mg. as is some times advocated. Otherwise, we may be defeating our own purpose in attempting to obtain a positive tuberculin test. The repeating of the test at a short interval of two or three days would be doing it during a period of temporary desensitization which requires more than a few days to disappear and to go from .1 c.c. of 1-1000 to .1 c.c. of 1-500 and .I c.c. of 1-100 might result in desensitizing the patient to tuberculin as in tuberculin therapy. One need not fear a severe reaction with a 1. mg. if a previous .1 mg. was negative.

Healed or Extinct Tuberculosis:

It is claimed that in an individual with a completely healed or extinct tuberculous infection, the tuberculin test will be negative and that in order to give a positive tuberculin test one must have at least one living tubercle bacillus present. On the other hand, the rapidly increasing incidence of positive tuberculin tests in children to its almost universal presence in adults should cause one to ponder whether the belief is correct or mere conjecture and if correct, then all individuals with positive tuberculin tests are suffering from some form of inactive or active tuberculosis. It must, therefore, indicate a negligible percentage of healed cases, particularly if we are to take into consideration a small percentage who have never become infected. Can it really mean that so few of us are able to combat this infection success-The explanation given occasionally when the tuberculin tests are persistently negative, and there are what appears to be calcific nodules in the hilum, is that the lesion is healed. However, it might be that every "calcific nodule" is not what it appears to be. This was brought out in an extensive research program sponsored by the

Oueensboro Tuberculosis and Health Association in co-operation with the Queens County Medical Society, to be carried out for a period of several years. The author is a member of the research committee and active in the work supervising the physical examinations of the children. X-rays were taken of the chests of 10,706 school children (7, 10 and 14 yr. groups) with a specially devised camera x-ray and paper film. Interpretation of the plates were made by an experienced worker and final interpretation by Dr. J. Burns Amberson, designating those showing sufficient amount of pathology from a tuberculosis standpoint to warrant a physical examination, at which time a tuberculin test was performed (intradermal I-1000). Of the 10,706 children x-rayed, 199 showed sufficient evidence of tuberculosis on xray to warrant a physical examination, and of the 199 children examined, 188 received the Mantoux test, of which only 105 (55.8 per cent) were positive.

It is, indeed, a comparatively small percentage of positive tuberculin tests in a group of children with highly suspicious tuberculous findings. indicates that x-ray alone cannot be depended upon to make a diagnosis of tuberculosis in children because of numerous conditions that may produce hilum adenopathy and central pneumonic infiltration that may more or less simulate Roentgenologically childhood tuberculosis. 7. 18 and 19

These conditions are:

- Post Scarlet Fever. (2) Post Whooping Cough.
- (3) Post Measles.
- (4) Chronic Bronchitis.(5) Bronchiectasis.(6) Lung Abscess.
- (7) Lues.
- (8) Hodgkins. (9) Foreign Body.
- (10) Asthma.
- (11) Anemia, (Leukemia)
- (12) Sinusitis.
- (13) Central Broncho Pneumonia. (14) Influenza. (15) Chronic Pneumonic Processes.
- 6. Other tuberculous conditions reported to produce a negative tuberculin test are:
 - Tuberculosis of serous membrane.¹¹
 - (2) Certain skin conditions believed tuberculous.12

There is much discussion at the present time, as to how concentrated a solution of tuberculin it is advisable to use. Hart,33 in his very complete monograph on tuberculin, used dilutions varying from .1 c.c. of a 1-10,000 (.01 mg.) to .1 c.c. of undiluted tuberculin (1:1 solution or 100 mg.). He calculated the percentage error to be expected with the various dilutions. "A negative intra-

cutaneous reaction with the standard dilution 1-1000 of tuberculin must weigh heavily against a diagnosis of clinical tuberculosis. The average error being 4 per cent in the series investigated. If, however, the slightest doubt remains as to the diagnosis, further tests with a 1-100 dilution should be performed, and if still negative, repeated with a 1-10 dilution. He states that a negative intracutaneous reaction to a 1-10 dilution of tuberculin excludes clinical tuberculosis with an error; that, judged from the present series, is very close to the minimum (2 per cent) obtained by using undiluted tuberculin. On this account and for technical reasons, a 1-10 dilution is the practical upper limit."

In 1911 Engle¹⁴ advised the use of a 1-10 dilution (10 mg.) and even undiluted tuberculin. With these larger doses he was able to obtain reactions in patients with cachexia and miliary tuberculosis who were negative to the more commonly used doses.

Happ and Casparis15 corroborated the findings of Engle with particular reference to children with tuberculous meningitis and miliary tuberculosis and stated that in their opinion the sensitivity to tuberculin is only depressed, but not lost. There are several reasons against the practical use of the more concentrated solutions of old tuberculin; namely, 1-10 and 1:1 (undiluted). The percentage error with a 1-1000 dilution is only 4 per cent compared with a minimum error of 2 per cent with undiluted tuberculin. Obviously, when a 1-100 dilution is used, the error is reduced still nearer the minimum 2 per cent, 2.75 per cent¹³ making a difference of a little less than 1 per cent. The vast majority of cases which compose that difference are cases that are obviously tuberculous, as advanced tuberculosis with cachexia, miliary tuberculosis, or tuberculous meningitis, requiring no positive tuberculin test to make the diagnosis. The use of a 1-10 dilution or stronger has often left me with more doubt than certainty as to the diagnosis because of persistent pseudotuberculin reactions that were difficult to distinguish from the typical tuberculin reaction which in itself has variations. Control solutions of glycerinated veal broth were used in the majority of cases in suitable dilutions in Hart's series. Skin reactions were obtained with the control solutions, 1-10 or stronger having all the macroscopic characteristics of the tuberculin reaction. However, the positive reactions in the controls, he stated, only occurred in tuberculous individuals.

Willis¹⁶ tested two groups: I group of 13 tuberculous patients and I of 15 healthy volunteers, with .1 c.c. of equal parts of glycerin and saline. This corresponds to undiluted tuberculin. Not a single individual tested failed to give a definitely indurated reaction in twenty-four to forty-eight hours, which was distinct for five or six days. The reaction was characterized by a

firm nodular induration; definitely pallid rather than red, and which might easily be mistaken for a true tuberculin reaction. In some there was vesiculation. Hence, in view of the fact that the percentage error with a 1-100 dilution is only 2.75 per cent compared with a minimum of 2 per cent with undiluted tuberculin, the difference be-

ing chiefly among the advanced and obviously tuberculous patients, and that reactions can be obtained in the 1-10 or stronger dilutions that are probably due to concentrated glycerin, I feel that the practical limit for ambulatory cases, and those not obviously with advanced tuberculosis should be a 1-100 dilution.

UNRESOLVED PNEUMONIA

By HAROLD J. HARRIS, M.D., WESTPORT, N. Y.

Read before the Medical Society of the County of Essex, November 9, 1932.

N the past five years virtually the only type of pneumonia that has occurred in this region has been the so-called grippe pneumonia. The sudden mode of onset with chill, high fever and pleuritic pain has been of rare occurrence. see a patient with grippe which actually merges into a frank lobar pneumonia has been common.

The other striking change has been the relative prevalence of unresolved pneumonia. The term 'unresolved" is used in preference to "delayed resolution" because it seems to be more accurately descriptive of the condition. The literature has contained very little on this subject in the past twenty years.

Because of the tendency towards this condition it has seemed wise to make routine radiographs as early as feasible during the convalescence from pneumonia. Physical findings nearly always are definite enough to make a diagnosis quite certain before radiography but occasionally small areas near the center of the lung may not give physical findings but will show up in stereoscopic radiographs.

The patient presents a rather typical clinical picture. There is usually a persistent cough, palpitation, lassitude, easy fatiguability, afternoon temperature, and a general slowing up of convalescence. Some are very ill and bed-ridden; pourse th

others work and complain only of palpitation,

dyspnea, and cough.

Treatment in this small series has been diathermy through the chest, often laterally as well antero-posteriorly, each treatment lasting from forty-five minutes to one and one-half hours, and given as nearly daily as possible. Obviously the electrodes have to be carefully placed directly over the aspect of the chest near which the patch exists. These patients improve so constantly under treatment that they do not have to be told that subsequent radiographs are showing a steady clearing. The mechanism of cure is by increasing circulation through the lung.

Case 1. Mrs. T. S. Age 35. Pneumonia complicating measles in December, 1924. Cough continued with occasional attacks of asthma, periodic temperature elevation and malaise. She consulted me on July 15, 1926, one and one-half years later. Physical examination showed a few crepitant rales over the middle third of the left chest posteriorly with increased whispered voice sounds and slight dullness. X-ray showed a hazy area in this part of the left lung. Six diathermy treatments given three days apart was followed by disappearance of all signs, symptoms and x-ray findings.

Case 2. Mrs. G. S. E. Age 49. Type 3 lobar pneumonia of the right base, onset May 29, 1931, following grippe. An apparent crisis occurred 48 hours later and was followed by a secondary rise of temperature which ran an irregular course up to 101 for another week, and then ranged to 99.6 for the next six weeks. Radiographs taken at the end of three weeks showed a patch over the lower half of the right lung diagnosable stereoscopically as unresolved pneumonia. A blood Wassermann taken the same day was 3-plus with both antigens. There was a history of syphilis 15 years before. Fifteen diathermy treatments, averaging one hour each, were given before the was no noticeable change on physical or x-ray examination during the first three weeks of treatment. Accordingly, diathermy was stopped but the sulfarsphenamine was con-

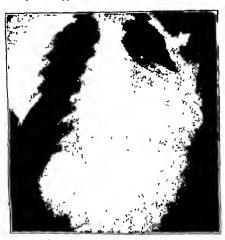

Fig 1—(Case 3) —Empyema and unresolved pneumonia, May 17, 1930

tinued. At the end of seven weeks roentgenogrants showed a practically normal lung, with the exception of accentuated root markings. The slow response in this case, as compared to the usual response to diathermy, was probably due to the long-standing st philis, as probably was the unresolved pneumonia itself. Cure was mainly ascribable to anti-syphilitic treatment, I believe.

Case 3. Mrs. C. C. Age 42. Ouset of right-sided type 3 lobar pneumonia, May 5, 1930, following grippe, followed closely by empyema, which diagnosis was confirmed by radiographs 12 days after the onset. Closed drainage was instituted. Drainage ceased in five weeks, but a daily temperature up to 101 continued. A clinical diagnosis of imresolved pneumonia co-existing with and following empyema was confirmed by further x-ray study. Diathermy had been given throughout the aeute pneumonia and stopped at the onset of empyema. It was resumed when drainage ceased, three times weeldy for four weeks, at the end of which time physical and x-ray signs had disappeared. Improvement in all signs and symptoms had been constant.

Case 4, Mr. C. P. Age 25. Onset of severe right-sided lobar pneumonia on February 18, 1931 following grippe. He was treated throughout with oxygen tent and diathermy, with lysis ending in normal temperature in six days Cough, dyspnea, tachyeardia and easy fatiguability persisted but there was no recurrence of fever. Radiographs taken four weeks after the onset showed an unresolved area in the outer third of the lower lobe of the right ling, the only part of involved lung tissue not thoroughly treated by diathermy throughout the acute pneumonia. The patient improved rapidly

after the first few diathermy treatments and all signs and symptoms disappeared within six weeks. Treatments were given with electrodes placed laterally, the smaller on the affected side to concentrate heat in the periphery of the right base.

Case 5 Mr. W. D. Age 75 Sudden onset of leftsided lobar pneumonia, March 5, 1931. No diathermy
was used hecause of the lack of electricity in the home
and the mildness of the pneumonia. A partial crisis
occurred in four days with a recurrence of pain, bloody
sputum and fever 48 hours later, subsiding by lysis in
six more days. Cough, dyspnea, dullness over the left
base, and distant breath sounds persisted. Radiographs
six weeks after the onset showed failure of resolution
of the outer lialf of the lower lobe of the left lung. Constant improvement in all signs and symptoms occurred
following the initiation of diathermy which was continued for the next four weeks.

Case 6. V. T. Female Age 9 Ouset of left-sided type 1 lobar pneumonia, January 17, 1929, following grippe, ending by erriss in six days and followed by empyeina five days later. Radlographs were taken two weeks after the onset and closed drainage instituted. Drainage stopped in 18 days but an irregular tempera-

Fig. 2--(Case 3).--Unresolved pneumonia (after drainage of empyema), June 25, 1930

ture up to 100, with cough, and evident toxacmia continued. Two weeks after drainage had stopped further radiographs showed a fan-shaped area of unresolved pneumoma in the upper third of the left lung. Diathermy was administered for four hours daily for five days and then for one and one-half hours each second day for another 10 days during which time all signs and symptoms disappeared.

Case 7. Mrs. E. N. Age 91. Onset of lobar pneumonia of right base August 11, 1931. Recovery was almost unbelievably rapid, temperature subsiding in 48 hours with no specific therapy. Moist rales persisted in the right base posteriorly. She was not seen again after the 15th of August until April 29, 1932, eight months later, at which time the history was obtained of frequent attacks of fever, cough, malaise and progressive weakness ever since the pneumonia. She had been a

relatively vigorous person, considering her advanced age, prior to the pneumonia. Physical examination showed crepitant rales, distant breath sounds and slight dullness over the site of the pneumonia. A diagnosis of unre-solved pneumonia was made but was not confirmed by x-ray because of the distance she would have had to travel to my office. She was last scen on September 5, 1932, and was in better general health. The physical signs had disappeared spontaneously after having persisted at least eight months. A decply placed patch may

Case 8. Mrs. J. N. Age 74. This patient was first seen on July 7, 1932, in consultation with her family doctor. There was a history of bronchial pneumonia in 1925, lobar pneumonia in 1927 and bronchial pneumonia again in 1931. Her present illness began in May, 1932, when she had symptoms of a grippe infection and ran a temperature upwards of 104 for 10 days. She was able to get up and about for a few days but there was a re-currence of fever and malaise. The cough had not subsided at any time. It was severe and productive of a frothy mucus. Her temperature continued up to 102 until the day she was seen in consultation. She had coughed up a mouthful of blood on two occasions and a diagnosis of pulmonary tuberculosis had been made by her attending physician. She was becoming progressively weaker.

Physical examination of this emaciated, bed-ridden

Fig. 3—(Case 8).—Unresolved pneumonia; right base, July 9, 1932.

woman showed a temperature of 99.6 and duliness with distant breath sounds over the right base posteriorly. A tentative diagnosis of unresolved pneumonia was made, tuberculosis seeming unlikely because of the basal location of the lung lesion. Five negative sputums had already been obtained and fifteen more taken subsequently were negative for tubercle bacilli as well as for evidence of mycotic infection. Pneumococcus Group IV was isolated. Radiographs showed an extensive unresolved pneumonia of the right base. Fifteen diathermy treatments were given between July 18 and August 23. The last radiograph taken September 5, 1932 showed a nearly cleared right lung. Her temperature had subsided to normal within two weeks of the time diathermy was begun and her cough had steadily lessened. She gained constantly in strength and weight. Improvement continued following the discontinuance of treatment, as usually does occur in such cases. When last seen on September 21, 1932, the patient seemed entirely well.

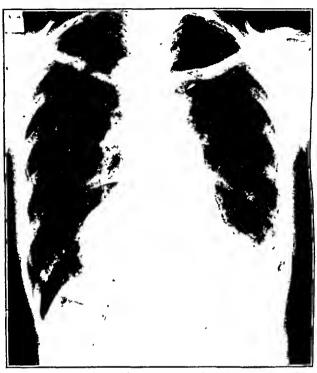

Fig 4—(Case 8).—After three weeks of treatment (improvement greater than is apparent due to over-exposure of this and subsequent radiograph).

Her cough had practically disappeared and she was able

to do her own house work.

This patient may actually have had an area of unresolved pneumonia since her first pneumonia seven years before. This area conceivably became reactivated by new bronchial infections three times subsequently and then, following her infection in May, 1932, failed to quiet down until treatment was instituted. I have purposely gone into detail in this case as I believe it illustrates many phases of the apparently ill-understood condition called unresolved pneumonia or delayed resolution of

pneumonia. Comment—Out of 32 cases of acute lobar pneumonia, selected at random from my files, eight had definite unresolved areas of lung tissue. Six out of eight cases of unresolved pneumonia were in patients in whom grippe had immediately preceded the pneumonia. In two cases empyema and unresolved pneumonia co-existed and the delayed resolution continued after the empyema was cured. In three cases diathermy had been used throughout the acute pneumonia. In all cases, except two, diathermy was used as the method of treatment of the unresolved pneumonia.

Conclusions

1. My limited experience would seem to indicate a higher incidence of unresolved pneumonia than is apparent from the literature.

2. Post-grippal pncumonia seems especially prone to the complication of unresolved pneumonia.

3. Physical signs and symptoms may not read-

ily suggest the diagnosis.

 Routine radiographs of all patients within a month following the onset of pneumonia would obviate the failure to recognize this condition.

5. Diathermy is a highly satisfactory method

of treatment of unresolved pneumonia. It may be administered in the home, even a portable machine of fair capacity sufficing, while x-ray therapy is usually not as readily available. Improvement begins very promptly after diathermy is begun.

 Recurrence of pneumonia within a few months or even years may well be due to reinfection of a neglected area of unresolved pneumonia.

A SIMPLE PROCEDURE FOR THE CURE OF RHINOPHYMA

By JOSEPH JORDAN ELLER, M.D., NEW YORK, N. Y.

From the Department of Dermatology and Syphilology, Broad Street Hospital, New York City

In view of the disfigurement and humiliation caused by rhinophyma, the treatment of this condition with good cosmetic results is of great importance to the one afflicted. Unfortunately many of the sufferers are led to believe that there is no cure for this ugly affliction. This is unfortunate as the technic for producing satisfactory results is rather simple.

Relation of Rhinophyma to Acne Rosacea.— As rhinophyma occasionally occurs as a sequela of acne rosacea, a description of their relationship

pathologically is hereby given.

Acne rosacea is more or less a sub-acute or chronic congestive disease involving the nose and neighboring parts of the cheeks and forehead,the flush areas of the face. The disease in its early stage begins as a passive hyperemia, which is followed later by dilatation and proliferation of the superficial capillaries. This telangietic element is due to an absorption of the elastic tissue in the blood vessel walls. At this stage the skin may be oily. The pustules in acne rosacea are more superficial than those seen in acne vulgaris. In rarer cases, the hypertrophy of the cutaneous and subcutaneous tissue becomes marked, and more or less lobulated masses appear, deforming the nor-mal structure of the nosc. This last stage is known as rhinophyma. The pores become patulons; and either sebum or pus, or both can be squeezed out of the tissues. The blood vessels continue to show considerable dilatation in this

Histologically then, rosacea in the early stage presents a dilatation of the capillaries with newly formed blood vessels, which may or may not be surrounded by an inflammatory inflitrate of small lymphocytes. This increased blood supply leads to edema and over-nourishment of the connective tissue. As the disease advances, deeper vessels are involved, and these may be surrounded in places by thick mantles of infiltrate made up of lymphocytes, epitheliod cells, and occasional giant cells. The condition being chronic and one which

is prone to recurrences leads therefore to considerable hypertrophy of the connective tissue and sebaceous glands, which together comprise the first signs of the later stage known as rhinophyma. Rhinophyma, histologically, consists of a marked hyperplasia of sebaceous glands and connective tissue plus many of the cellular elements found in acne rosacea.

The simple red enlargement of the end of the nose is an exaggerated form of acne rosacea which may or may not be a beginning rhinophyma. Rhinophyma which is removed by some surgical method in addition to other therapy does not recur, whereas acne rosacea which is treated by local applications and other palliative measures, such as attention to gastric and nervous disturbances, is prone to recur, depending on the latter conditions.

The four cases of rhinophyma herein reported are examples of the good cosmetic results obtained by a relatively simple procedure. The superfluous tissue is pared off under local anesthesia until the nose is shapely. Later when the skin has grown over the denuded areas, it is treated by applications of roentgen rays, or trichloracetic acid or phenol.

In each case, the patient regained a shapely nose without conspicuous scars.

Report of Cases

Case I. A. L., male, aged 80, consulted me December 30, 1929, complaining of a disfiguring enlargment of the nose. The condition was rhinophyma of twenty years' duration, and progressively becoming worse. On palpation, the nodular growths were found to be pliable but rather firm in consistency. They involved the tip and both alae of the nose and consisted of several irregularly lobulated masses, varying in size from that of a pea to that of a marble. One large nodule arising from the left ala was the size of a lemon and liung below the other portions of the mass. These combined nodules formed an irregularity of the mass. These combined nodules formed an irregularity of the mass.

lar collection the size of an orange, with many pea to marble size satellites projecting from the main mass.

Under local anesthesia with 2 per cent novocaine solution, the redundant bulbous tissue was pared off until the nose had a shapely proportion.

Six weeks later four roentgen ray applications in doses of one half unit every three weeks were made to the alae of the nose. One month after the course of X-ray therapy, phenol solution was applied to the raised granulating area. Five months after the paring off procedure trichloracetic acid was applied. This had the effect of minimizing the scars. The cosmetic result is shown in Figure 1.

Fig 1
Before and after treatment, Case 1

Case 2. J. E. M., a realtor aged 56, consulted me September 23, 1930, complaining of disfiguring enlargement and redness of the end of his nose. The condition was obviously rhinophyma. It started ten to fifteen years ago, when the end of the nose became reddened and pus would at times exude from the patulous follicles. Since then the extremity of the nose gradually became larger and redder.

The nose was pared down to normal shape under 2 per cent novocaine infiltration. A petrolatum dressing was applied.

Later, roentgen ray applications, one half unit, were made to the sides of the nose, generally at intervals of ten days to two weeks. On several occasions the Grenz ray, one eighth unit, was used. This treatment had the effect of minimizing the scar.

The cosmetic result is shown in Figure 2.

Fig 2
Before and after treatment, Case 3

Case 3. A.E., housewife, aged 61, was seen May 5, 1931, complaining of the disfiguring enlargement of her nose. The condition was a typical rhinophyma as shown in Figure 2. She stated that the nose growth began four or five years ago and gradually grew to its present size. It caused no pain or discomfort but occasioned extreme humiliation. Except for this condition, the physical examination was negative.

The nodules were excised with the scissors and the extremity of the nose was pared down to normal proportions with the scalpel. Bleeding was easily controlled by compression and tying the vessels with catgut The skin from around the base of the growth was utilized to cover the raw areas after excision of the mass. Finally, a petrolatum album dressing was applied with pressure.

Simple dressings, curetting of the edges of the wound and applications of phenol solution to the elevated granulations, were the only after-treatment required in this case The cosmetic result is shown in Figure 2 taken ten weeks after treatment.

Case 4. H. R., a tool maker aged 56, presented himself on May 22, 1932, with a nodular swelling of the tip and ala of the nose about the size of a walnut. He had had acne at 14 years of age, which disappeared from his face but persisted on his back and shoulders. The end of the nose had been red for ten years and enlarged for the past four years

The enlargement of the nose involved the tip and both alae, principally the right It was irregular in outline and showed many patent ducts. To palpation it felt soft and cystic. On pressure, a yellowish material exuded from the follicles About the bridge of the nose and the nasolabial

folds there were many telangiectatic blood vessels

The treatment in this case was similar to that of the other cases and included excision of the nodules and reshaping of the nose under novocame anesthesia. The after-treatment utilized Roentgen ray applications. The cosmetic result was excellent.

The method described is simpler and gives better results than the old technique of decortication which requires skin grafting from distant points

It is much quicker and surer than the method of gradually destroying the rhinophyma by the high frequency current

SUMMARY

A simple procedure giving excellent cosmetic results in rhinophy in a described. To obliterate the scars, roentgen rays and tirchloracetic acid or phenol may be used in after treatment. The four cases reported illustrate the results to be expected.

A GROUP STUDY IN HAY FEVER* By HARRY S BERKOFF, M D, NEW YORK, N Y

DURING the hay fever season of 1932 an opportunity was offered to treat a group of subjects during their actual hours of work in the various departments of a large mercantile organization. Their observation under these somewhat unusual circumstances was productive of data and results that seemed to warrant this summary review.

Ninety three subjects reported at different times to the clime which continued in operation from March to November, meeting twice weekly for periods of two and one half hours. At the first visit a history was taken, tests performed, and treatment, when indicated, commenced.

Of the total number 59 were able to report for a complete course of treatment, while in the remaining 34 the treatment was incomplete due to various reasons. It is the former group that forms the basis for the first part of this study.

Completely Treated Group (59)
Females 38 (644%)
Males 21 (356%)

Occupation

Sales 24 Non sales 35

It is interesting to note that in the sales group the predominiting departments represented were dresses, linens, coats, furs and other fabrics all though, as will be shown later, this was without effect upon the ultimate results of treatment. The non-sales were mostly clerical workers

13	1		

Preceding Course:

23 reported no change in the severity of their hay fever.

19 reported an amelioration of their symptoms.

14 reported an increasing severity of their ymptoms.

It is noteworthy that in the group that was improving (19) only 2 had had their hay fever for less than 5 years, the majority having had theirs for ten years or more.

Degree of Sensitivity:

In recent years the grading of patients according to the degree of their sensitivity by skin tests has become a valuable index. Our group was distributed as follows in the order of decreasing sensitivity:

Α	2
B+	16
В	28
С	10
D	1

No relation was apparent between the degree of sensitiveness and the duration of the hay fever. While the majority of the most sensitive individuals were in the less than 10 year group, there were included also those who had their hay fever for 20, 23 and 27 years, respectively.

Relation of Asthma:

14 had asthma accompanying their hay fever at different times.

45 were free from it.

2 complained of asthma after the cessation of hay fever.

Free Intervals:

12 reported brief intervals of freedom from hay fever of 1 to 2 years' duration. Among the ascribed reasons for this were: residence abroad, pregnancy, and previous treatment.

Other Allergy:

The allied allergic conditions were found distributed as follows in our group:

Urticaria:

Present in 14

Eczema:

Present in 7

Angioneurotic edema:

Present in 2

Five individuals had more than one of these conditions.

Aggravating Factors in Relation to Hay Fever: (From past history)

Dust:

Increased symptoms in 45. Was without effect in 13.

Cold:

Increased symptoms in 7. Diminished symptoms in 18. Was without effect in 34.

Heat:

Increased symptoms in 35. Diminished symptoms in 2. Was without effect in 20.

Dampness:

Increased symptoms in 11. Diminished symptoms in 18. Was without effect in 25.

Drought:

Increased symptoms in 18. Diminished symptoms in 8. Was without effect in 27.

Exertion (marked):

Increased symptoms in 24. Diminished symptoms in 1. Was without effect in 33.

Emotional Upset:

Increased symptoms in 9. Diminished symptoms in 1. Was without effect in 47.

11 complained of more symptoms at night. 27 complained of more symptoms during the day.

21 were affected equally by day and night.

History of Colds:

Under this heading are included the usual upper respiratory infections and doubtless many of the milder sinus and bronchial involvements, causing, in the majority of instances, little, if any, disability.

2 were entirely free from colds.

40 were subject to an occasional cold.

13 suffered from frequent colds.

10 were previously subjected to operations on the nose, such as submucus resections, antrotomy and polyp removal.

Previous Treatment:

29 were previously tested.

20 were previously treated and 5 others incompletely for a period of 1 to 5 years; the majority for 2 years.

The results of such previous treatment showed:

17 benefited

2 unaffected

2 aggravated (1 incomplete treatment)

Family History:

A distinct familial tendency to hay fever or the other conditions allied to it (asthma, eczema, urticaria. angioneurotic edema, migraine, etc.) is well recognized. In our group the incidence was

rather high, being present in 29 (50%). Of these, 7 patients had 2 members of their families subject to the above conditions, 5 had 3 relatives and 1 had 4 similarly affected.

General Health

53 reported being in good general health 6 were in only fair health

Past Medical History

A general survey of the past health history showed the following conditions present most frequently in our group

Hypertrophied tonsils Sinusitis Otitis Dysmenorrhica Malnutrition Furunculosis

One of our patients is a diabetic, another his a healed pulmonary lesion

Tests

Tests were performed by the intracutaneous technique routinely with the common pollens, and when indicated with the trees and other grasses by the scratch method. In several cases eye tests were resorted to. The distribution of positive tests was as follows.

Plantain 5 Timothy 15 Ragweeds 50 Orris root 20 Dust 34

The last two were added because of their alleged aggravating tendency

Tested to other common grasses
13—10 were positive
1 ested to combined trees

10—1 was positive

Lye tests were invariably negative

Treatment

This was limited to extracts of plantain, timothy and the ragweeds, the concentrated solutions being obtained from one of the local biological laboratories and dilutions made whenever required

48 individuals were treated weekly 11 individuals were treated semi weekly

Absences vacations and over-lapping in the case of bi-sersonal patients were factors in disturbing the schedule. In this group treatment was continued well into the season, as is the usual practice.

Reactions

Occasionally systemic reactions after treatment may occur. These are of the nature of a hay fever or asthmatic reaction and, if watched for, can be readily controlled. There were six

reactions and only one of any degree of severity The very low incidence of reactions in our group was probably attained

By a somewhat more prolonged period of treatment, which allowed a more gradual step

ping-up of dosages,

By a conservative maximum of dosage, and By a short period of rest (about 20 minutes)

in the clinic after treatments

The last is of importance when we consider the varied environments and occupations our patients returned to So that while treatment of a large group such as this in the course of a day's activity and return to it, rather than to a period of restful recovery at home may have been somewhat of an experiment, it was decidedly without any of its risks

Aurihary Treatment

Thirty-five individuals resorted in varying degrees to medicinal preparations for such symptoms as occurred at the height of the season These included adrentin sprays, ephedrine and atropine

Results

At the end of the season questionnaires were submitted for a subjective estimate of results

No hay fever symptoms 2
75% or more improved 34 (59 6%)
50% improved 17
25% improved 4
2 interported because of resignation

In other words, 631% of completely treated patients had 75% or more of improvement

Our own estimate of results, with few exceptions, closely approached the individual responses obtained

From the standpoint of occupation in relation to unsatisfactory results the following is of interest

In the 25% improved group, of the 4 subjects 2 were secretaries, 2 sales persons only one of whom was exposed to a possibly irritant inhalant

In the 50% improved group (total of 17) the division was almost equal between those who may have been exposed to irritating inhalants such as cotton, fur, woolen, etc., and those who were not

In the group giving history of frequent colds, 3 of whom had been subjected to intransal operative therapy, there was no definite influence on the result of the hay fever treatment 70% of all those who had similar operative interference reported 75% or more improvement in their hay fever. However, in those who developed colds during the late treatment period or in the season itself, the impression was that the results were less favorable.

In regard to extra pollen sensitivity only orris root and dust are available for notice in this group. The results of treatment with pollen alone in those also sensitive to orris root were as follows:

No hay fever 175% improved 1250% improved 525% improved 2

The results of treatment with pollen alone in those also sensitive to dust were as follows:

No hay fever 1 75% improved 22 50% improved 8 25% improved 2

While the numbers are too small to draw any conclusions, it would seem, however, that sensitivity to such common substances as orris root and dust was without notable effect on the ultimate result of treatment.

Two patients who gave negative skin and eye reactions and were treated on basis of history and allergic family tendency had 75% relief of symptoms.

Complications in the Course of Treatment:

Colds (nasopharyngitis, tonsillitis, laryngitis.)
Coughs—some of asthmatic character.

Skin eruptions. Gastric upsets.

One case developed an acute antrum infection which had to be drained.

The outstanding complaint was, of course, the sneeze, but it is interesting from a study of symptomatology that nasal obstruction was frequently the only complaint and that among those who probably were developing the hay fever for the first time this year, that was the only presenting symptom.

Loss of Time from Work:

Four women lost a total of ten days from work, three of which in one case were directly attributable to a sinus re-infection.

Laboratory Studies:

Differential blood counts were done on 63 patients. Only two showed an absence of eosinophiles. The highest count of these was 12%. Thirty-five patients had 3% or more of eosinophiles—the average was 3.9%. The polymorphonuclear count ranged from 45 to 80% with an average of 59.3%. The lymphocytes ranged from 14 to 48% with an average of 33.1%.

X-rays:

No routine plates were made, but in five individuals of this group who were x-rayed in the course of other studies, an increase of bronchial markings was found.

Post-Seasonal Retesting:

In 22 instances skin tests were repeated at the

end of the treatment. Only four showed a definite diminution in the size of the reaction, the rest remaining the same. There was no correlation observed between the lessening of skin reactivity and the extent of symptomatic improvement on treatment.

The Incompletely Treated Group:

Thirty-four individuals were included in this varied group. Some could not or would not continue treatment, some resigned, a few waited for the onset of hay fever before reporting, and 12 came for diagnosis with symptoms for the first time this year. Here also the women outnumbered the men, 19 to 15. The numbers were evenly divided between selling and non-selling departments. The ages ranged from 20 to 48. The duration of hay fever in this group was from 1 to 26 years. The classification of sensitivity was as follows, in decreasing degree:

A 1 B+ 7 B 13 C 5 D 1

Seven gave a history of accompanying asthma and four of asthma at other times of the year. Seven were subject to urticaria, two to eczema and one to angioneurotic edema.

Four gave no history of colds, twenty of an occasional one, and ten of frequent colds.

Here even a higher familial history was found, namely 64.9%.

Only two in this group were previously treated, and with good results.

Because of the inadequacy of treatment in this group, the results are not suitable for analysis.

In a sufficient number of instances to warrant notice considerable improvement in symptoms was afforded those who reported during the active season and received small dosages at weekly or semi-weekly intervals. No actual effort was made to desensitize or hyposensitize these patients, among whom were included first-year subjects as well as those of many years' standing. No explanation is offered of the process underlying the relief noted, but the fact is worthy of further observation.

Summary:

A group study is reported of preventive hay fever treatment in the case of 93 individuals in the course of their daily activities, 59 of whom completed their treatment and 34 of whom did not.

A total of 1414 injections was administered.

Ouestionnaires about results were returned

Questionnaires about results were returned from all but two of the completely treated group.

Results:

No hay fever 2 75% or more improved 34 (59.6%) 50% improved 17 25% improved 4

In other words 63.1% of completely treated patients had 75% or more of improvement. The remaining 36.9% must, strictly speaking, be regarded as the poor result of treatment. It did not appear that such factors as the occupational environment or exposure to inhalant irritants, or conservatism of dosage played a marked role in this. The explanation must probably be sought in the individual variant of the allergic constitution.

From the standpoint of group treatment, how-

ever, if we bear in mind the existence of a certain pressure because of the need for time economy, that our patients came directly from their varied occupations and returned to them only after a hrief period of rest, that interruptions due to vacations and business were frequent, and that a certain conservatism of dosage had to be maintained because of the very nature of mass treatment, the results, even in only a moderately severe season, would seem to endorse the present therapeutic procedure.

Until such a day as a hetter understanding of the allergic tendency and mechanism is to be had and better methods of prevention and treatment are evolved, hyposensitization, for those, at least, who must live and work in the pollen atmosphere,

still remains the method of choice.

ACNE VULGARIS*

A Review of 200 Cases with Reference to Classification and Treatment By ALBERT R. McFARLAND, M.D., ROCHESTER, N. Y.

E present in this paper a study of 200 cases of acne vulgaris observed over a period of about five years. No case was included in which a shorter time than one year had elapsed following treatment. Follow up consisted mostly of personal observation but sometimes by letter or phone.

An attempt is made to classify the types and to

evaluate the various forms of treatment.

The accompanying tables present a statistical résumé although we realize the fallability of statistics and believe a large personal element must necessarily enter into the compiling of any statistics on acne. Certain impressions gained by seeing many cases are however in general confirmed by the statistical study.

Chart I indicates the types and duration.

CHART I

Type and Duration

Duration 6 months to 20 years.

92% began at or near puberty. 8% pustular acne indurata.

24% comedone type.

68% mixed type.

Chart II indicates the treatment received prior to our seeing them.

CHART II

Previous Care

32% on low C. H. diet with no improvement. 84% frequent soap and water or steaming.

24% said better in Summer.

38% had used some local medication.

8% had had some actinic therapy.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May, 1932

I.D., ROCHESTER, N. Y.

Chart III indicates the type of treatment used.

CHART III

Treatment

6% phenol only used.

68% x-ray, lotia alba, diet, surgery and local

18% quartz light, lotia alba and surgery. 8% miscellaneous.

Chart IV shows results obtained.

CHART IV

Results

82% good result after 1 to 11/2 years.

18% varying degrees of improvement. Almost 100% results with phenol in indurata type.

Little if any improvement with diet alone. Objectionable x-ray effects 4%.

The outstanding fact in acne vulgaris, which is obvious to anyone, is that acne is a disease of the post adolescent age and undoubtedly closely related to changes in glandular function which occur at this period. Until the disease can be approached from this angle successfully, the treatment of acne must remain the treatment of symptoms. Acne is not so much a disease of pathology as it is of physiology. At the adolescent age the sebaceous glands become hyperactive, the secretion is excessive, the ducts become dilated and clogged and secondary infection finds a fertile soil in which to grow. We use local measures to try to decrease the activity of these glands to keep them free from infection and to establish drainage but until we can control the chemical stimulant which starts the process, we must rely upon symptomatic treatment. The role of local infecting organisms is doubtful as studied by Ketron & Brown.

For convenience of study our cases are classified as, comedone type, pustular, indurated type and mixed type. This classification is of course based upon the preponderating type of lesion and overlapping frequently occurs.

The armamentarium of treatment used consisted of x-rays, quartz light, acne surgery, diet and hygienic measures, vaccines and bacteriophages, parenteric use of phenol, glandular therapy and local applications to the skin. As will be pointed out later, the choice of treatment or combinations of treatment depended upon the

type encountered.

Having seen from this statistical study what may be reasonably expected in the management of acne cases provided an intelligent line of procedure is adopted which is suitable to the individual case, we should like to devote the remainder of the paper to a detailed consideration of the various phases of treatment in selected types of cases and some lessons which seem to have been learned.

X-ray Therapy

From what deductions may be made from this series and from personal observation, there seems to be little doubt but that x-ray treatment is the most valuable and effective single agent available. However, like most other therapeutic measures which are of value it has its drawbacks and limitations and is certainly a two-edged sword. This is particularly true in the hands of the inexperienced and perhaps too often in the hands also of presumably competent dermatologists. It would seem timely therefore to call attention to some of the dangers to guard against in using x-rays.

In the first place we believe that cases should be selected carefully for x-ray treatment and should not be subjected to a mechanical routine just because the diagnosis of acne is made. should be borne in mind that many cases of acne are very mild and undoubtedly clear up spontaneously or with very limited therapy. For those who are of a platonic temperament and who are not particularly annoyed by the condition one can afford to follow an expectant program of treatment. Often the assurance that improvement is likely to take place as they get a little older will satisfy these individuals. It would seem undesirable to subject that class of patients to intensive x-ray therapy where a little applied psychology would tide them over the acne age. In only 68% of our cases was x-ray found to be indicated.

If it is decided that x-ray therapy is indicated it has been our impression that patients get a better final result if the treatment is not hurried. As a rule $\frac{1}{4}$ to $\frac{3}{8}$ skin unit doses every two weeks, depending upon the type of skin, gives better re-

sults than ¼ skin units weekly. X-ray effects develop slowly and time should be given we believe for observing a gradual, though, slow improvement. The very fact that the patients are kept under observation longer affords the physician an opportunity to direct treatment as indications arise.

The fact that epilation of the scalp in tinea does not begin for about two weeks after exposure would indicate that this length of time is required to get the full therapeutic effect.

In general we are in accord with the views of Lord & Kemp² that a maximum total x-ray dosage of $2\frac{1}{2}$ to 3 skin units should be about the limit.

Again a great deal can be done by carefully directing the rays to the parts most affected rather than a routine of one front and two side exposures.

One must be on guard against idiosyncrasy. The general type of skin, texture and pigmentation is of some importance in determining the amount of x-ray likely to be tolerated. The end results would seem to indicate that skins which show an early tendency to pigmentation and freckling do not tolerate x-ray well. Males are apparently more resistant to the rays in general than females, and young individuals do not tolerate a dose which may be given adults. Occasionally a case was encountered in which the patient noted a slight erythema after a treatment which should not cause an erythema. These patients should be watched closely. Personally I have never observed the erythema myself after a 1/4 skin unit dose. It is evidently quite transient if it occurs.

A rather susceptible area in my experience has been about the angles of the mouth and chin in women. This is the region where "crows feet" normally develop and we have observed several cases where there seems to be a lack of subcutaneous tissue and wrinkling in this area where areas such as the forehead and cheeks are not affected. This should be borne in mind and as little as possible given to this area.

It was our custom routinely to cover the eyes with lead glasses and to use leaded rubber over the chest and thyroid region. Close screening with lead did not seem to be necessary and in fact undesirable, as slight lines of pigmentation might show where the lead had been placed and a bad cosmetic result secured.

When radiating the back or chest the areas of exposure should not be too close together. In small individuals with narrow backs there may be too much overlapping. I have seen two cases in which x-ray atrophy occurred in the region where overlapping had taken place.

The technique used in most cases was to give a course of about 6 treatments at 2 week intervals using from 1/4 to 3/8 skin units at each treatment.

Regardless of immediate results treatment was then discontinued. The effects of a rays extend over a long period of time and it was found advisable to tell the patients of this fact. A fair percentage of the cases observed showed only meager improvement immediately after a course of treatment but 6 months later results were more apparent A second course was not given if it could be avoided and at least not before 6 or 8 months had elapsed. In no instance did we observe any deleterious effect after one course of treatment but after two courses there was occa sionally some evidence of atrophy cases we feel that the disease itself is so disfiguring that a slight amount of atrophy is justifiable in combatting the disease just as an abdominal scar is a necessary evil in the removal of an appendix. Finally it should be emphasized that if results are not obtained after a reasonable amount of treatment recourse should be had to other methods of treatment. Three or four eases were encountered, among earlier patients clinelly, where our enthusiasm carried us on to kill or cure and where the result was not good. If carried too far we feel that the skin becomes atrophic and actually loses its resistance to progenic infection and licks reciperative power

Personally I have not encountered a case where telengiectasia developed with as little as a total dosige of 3 skin units provided the dosige was properly spaced although other derinatologists

have reported such cases

Quartz Light Therapy

Treatment with the air-cooled mercury vapor quartz light was used in a large number of these cases either alone or combined with x-ray Two methods may be employed. One is to use it locally only on the areas my lived. The other is to use it all over the body for its tonic or systemie The former method was used in most An attempt was made to give a mild erythema with some exfoliating action The me ehanical exfoliation seems to be of benefit use is indicated in cases with a tendency to superficial progenic infections where an autibacterio cidal effect is desired. It is also of value in those types which have a combined greasy seborrhea and acne Where it was used in conjunction with x ray it has been our practice to give a course of treatment with the quartz light some months after the x-ray, or if two 1-ray courses were given between these courses Oceasionally a ease was encountered where the individual had very little if any acne but was phobie in regard to it or developed an inferiority complex Management of these eases is made easier by the use of quartz light even though it may be little more than a form of psycho-therapy One realized that he is at least doing no damage by treatment

Whether the generalized use of quartz light

has enough benefit to warrant its use, I am not eertain A rather large series of cases have been treated by this method at the University of Rochester Medical School with the cooperation of Dr A fair amount of improve-Stafford Warren ment was noted in most cases but frequent treatments over long periods of time seemed to be required to produce any results Perhaps the tonic effect increases resistance to staphylococci but I believe very little is accomplished in the severe eomedone type Where cases are moderately severe this technique seems to us rather uncertain and the economic factor involved in long contimued and frequent treatments renders it almost proliibitive in private practice

We therefore found quartz light of value in mild cases, especially in young individuals, in superficial purcular types, and as an adjunct to 1-ray therapy. Although relatively safe, its effi-

ciency is much less than r-ray

Acne Surgery

Acne surgery we found to be very valuable in many cases. A sharp cataract knife and a come done expressor having a fairly large opening are the instruments needed. Asepsis should be followed in their use as failure to do so may lead to added infection. In the comedone type acne surgery is especially indicated. An attempt should be made to cause a slight scar which upon contracting decreases the size of the duct. The contents should also be expressed as thoroughly as possible Acue surgery is most effective in the early course of a ray treatment. Later on it be comes more difficult to express the contents due to action of the rays upon the glandular tissue We have frequently found it almost impossible to express the contents of comedones after a course of r-ray as the sebaccous material becomes inspicated and firmly impacted. In the deep indurated pustular type it is usually essential to evacuate the contents

A fair number of eases are encountered where only an occasional deep sented pustule appears, the skin being otherwise normal. Such a type is often found in women where the lesions appear only at the menstrial time. Acre surgery alone may be sufficient for such a case and keep it un-

der control

Parenteric Phenol

Since the report of Matusis and Pavlov³ regarding the parenterie use of phenol we have been interested in following the results after its use A 3% aqueous solution is used intramuseularly in doses of 1 to 2 cc two or three times a week. The first ease in which we used it was that of a voing man 23 years of age who had a very severe pustular indurated type on the face and neck. There were numerous pockets 2 to 3 cm in themeter. He had had the limit of 1-ray, several

courses of quartz light, acne surgery and local applications. As a therapeutic test he was given 1 to 2 c.c. of a 3% solution of phenol every third day. All other treatment was suspended. At the end of 3 weeks at least 75% benefit was obtained. Gradually the interval of treatment was lengthened. At the end of 3 months he was absolutely free from lesions and has remained so. then we have had 7 similar cases. It is our practice now to use it in severe pustular types in conjunction with other forms of treatment. The results seem to be most striking in acne indurata but we feel that it is also of benefit in milder pustular The urine should be checked frequently as we have occasionally noted a trace of albumin after eight or ten injections. This, however, quickly disappears upon stopping the drug.

Diet

A tradition has become established that acne is made worse by diets rich in carbohydrates, fried foods and condiments. From our series it would be difficult to say how much benefit is derived from such a diet. From a careful history it was found that 32% of our cases had voluntarily been on such a diet before consulting us and in a much larger percentage no excess of these foods was being used. In spite of this practically none had noted any improvement. Theoretically a high blood sugar should encourage the growth of staphylococci but certainly in our experience acne cannot be materially affected by diet alone. Of late we have been cautious in stressing this point as many young women get the impression that if such a diet is of benefit they will eat no starches at all in a frantic effort to obtain improvement. We have felt that the general resistance of quite a few cases has been impaired by overdoing this restriction of diet.

General hygienic measures such as regular meals, plenty of time to eat, keeping the bowels regular, sufficient sleep and plenty of fresh air. sunshine and exercise are probably of value but it seems questionable if a marked restriction of diet is justifiable. At least the mental makeup of the patient should be evaluated before giving any drastic instructions in regard to the limitation of diet.

Local Care of the Skin

Two objects should be kept in mind in caring for the skin in acne. One is to keep the surface as free as possible from staphylococci and the other is to use applications which will either mechanically clear out the pores or to act as an astringent. Cold crèmes are contra-indicated as they really add to the accumulation in the pores. Frequent washing of the face with soap and warm water followed by a cold splash are of advantage. The usual lotia alba has proved to be quite satisfactory as a local application because of its astringent and mild exfoliative action. Inci-

dentally a number of control cases were run with and without using lotia alba together with x-ray. No appreciable difference could be noted in the two series as to the effect of x-ray.

What would seem to be most needed is a good solvent which would dissolve the fatty plugs without injuring the skin. Acetone and alcohol seem to only partially fulfill this requirement.

Coincident care of the scalp as well as to the skin of the face is important. Many cases were encountered with marked seborrhea of the scalp. The acne clears up more rapidly if this condition is corrected at the same time.

Vaccines and Bacteriophages

Both autogenous and stock vaccines were used in a number of cases but no striking results were noted. They would appear to us to be of questionable value.

A few cases were temporarily improved by local applications of staphylococcic bacteriophage. The cost is however of some economic importance and patients often will not take the time to use it properly.

Glandular Therapy

As we stated at the outset we feel that acne is primarily a disease of abnormal physiology probably bound up with the glandular system. Unfortunately this field seems as yet too poorly understood to be of great value.

In selected cases we have used mixed glandular therapy and have frequently been encouraged by the results. Certainly, however, much more must be learned before this type of therapy can be intelligently applied.

Conclusions

- 1. By a proper selection of therapy, satisfactory results may be obtained in approximately 82% of cases of acne vulgaris.
- 2. Emphasis should be laid upon conservative methods of treatment as about 30% may be tided over the acne age without the use of x-ray.
- 3. X-ray is the most valuable single adjunct in the treatment of acne but should be used only in selected cases and the total dose should in all cases be kept well under the point of producing objectionable sequale.
- 4. The parenteric use of phenol promises to be of value in the pustular indurative type.
- 5. More emphasis should be placed upon general hygienic measures than on restrictive diets as damage may be otherwise done due to malnutrition.
- 6. The management of acne in general is based upon symptomatic treatment. The probable advances in the future would seem to be in the field of glandular therapy.

A CASE OF TULAREMIA IN WHICH NO LOCAL LESION DEVELOPED AT THE SITE OF INJURY

By EDGAR R. MAILLARD, M.D., ALBANY, N. Y.

From the Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

N February 6, 1931, a middle-aged man, a specimen of whose blood had agglutinated B. tularense,1 came to the branch laboratory of the New York State Department of Health to have specimens collected for examination. At the time, it was noted that the patient had an ulcer on the plantar surface of his left thumb. Material collected from the ulcer was suspended in sterile physiological salt solution and injected subeutaneously into two guinea pigs. The animals died on February 12 and were subsequently autopsied. Exudate was found in the plcural and peritoneal cavities with vascular engorgement and petechial hemorrhages throughout. B. tularense was isolated from the liver, lung, spleen, kidneys, and from blood taken from the heart, as well as from the pleural and peritoneal exudates and the urine. While performing the autopsy, the pathologist accidentally pricked his finger with a thumb tack which held the guinea pig on the board. The gloves were immediately removed and the hands washed with soap and water and rinsed in alcohol.

On the seventh day following the accident, February 19, a feeling of general malaise with fever, chills, and headache was experienced. The symptoms became more pronounced, particularly the headache, which was postoccipital in location and intensely gripping in character. The duration of the fever, which was remittent, was about three weeks, and the temperature ranged from 99°F. to 104°F. The daily peak, which usually occurred in the early afternoon, was preceded by chills and followed by profuse sweating and prostration. The pulse rate fluctuated between 100 and 130 during the height of the febrile reaction.

A complete physical examination revealed no abnormal findings. No lesion developed at the site of the accidental prick nor was there any palpable enlargement of the regional lymph glands. These features of the case seemed of particular interest since a lesion so generally develops at the site of infection and the enlargement

of the regional lymph nodes is so characteristic of tularemia when a wound has occurred. Francis² has reported a number of cases of tularemia, among laboratory personnel, without manifestations of a primary lesion or of glandular enlargement. Possibly the prompt use of an antiseptic which would remove nost of the pyogenic cocci may inhibit the development of a lesion at the portal of infection. Convalescence was fairly rapid with complete recovery at the end of the seventh week.*

Laboratory Examinations

Several specimens of whole blood were eolected from the patient at various times for serological examination. A specimen collected on February 21 did not agglutinate B. tularense; a specimen eollected on February 27 gave a partial agglutination reaction (2+) in a 1:40 dilution of the scrum. Definite agglutination (3+) of B. tularense was obtained with blood specimens collected March 10 and April 19, in dilutions of 1:640 and 1:1280 respectively. A specimen examined in August, 1932, gave a definite agglutination reaction of 3+ in a 1:80 dilution. Agglutination tests with B. abortus and B. proteus X 19 were performed on all the specimens; no agglutination was obtained in any instance.

Summary

A case of an accidental infection of a laboratory worker with *B. tularense* is reported. The clinical picture was that of an infectious disease, but not outstandingly typical of any. This case illustrates the importance of a complete history as an aid in determining the type of laboratory examinations to be undertaken. The reliability and practicability of the agglutination tests as a method for differentiating infectious diseases are well exemplified.

*This case is one of the twelve included in a report by Gilbert and Coleman: "The Incidence of Tularemia in New York State," Amer. Jour. Pub. Health, Dec., 1932, 22, 1249.

TRICHINIASIS, WITH RECOVERY

By MAURICE DAVID KENLER, M.D., AND JACOB JOSEPH SILVERMAN, M.D., TOMPKINSVILLE, STATEN ISLAND

From the Staten Island Hospital Medical Service, Dr. George Johnson, Chief of Service.

In this age of close and rigid public health supervision the impression prevails that trichiniasis is a rather rare and unimportant disease. The medical service of the Staten Island Hospital recently had a case of trichiniasis which bears interest both from a medical as well as from a public health standpoint.

The statistics concerning this disease are interesting. Staten Island has a population of about 160,000. As far as can be determined this is the first case ever to be reported to the Staten Island Board of Health. Examination of statistics for the rest of New York City disclosed that forty-eight (48) cases of trichiniasis had been reported in 1932. The State Department of Health furnishes the following figures:

Year	New York City	Upstate	Total
1930	21	3 9	60
1931	33	57	90
1932	48	23	71

In 1932 there were 237 cases and 15 deaths reported in the United States. These figures are for the first eleven months and are by no means complete since many states do not consider trichiniasis a reportable disease. In fact New York City has been reporting this disease for only the past three years.

Case Report: Mrs. L. M., age 20, an Italian housewife, was sent into the hospital by her family physician on December 14, 1932, for diagnosis and treatment. Her chief complaint on entry was headache of two weeks' duration. She stated that she had been in good health until two weeks prior to admission when she gradually developed an intermittent generalized headache. About one week prior to entry she developed swelling of her eyelids, face, and lower extremities in the order mentioned. During the past week she had complained of a very severe itching of the skin, ringing of the ears, and black spots before her eyes.

Her past history was unimportant. She stated that she had always been well. She had been married for nine months. She had lived on Staten Island practically all her life. Questions concerning her diet in the past month became of paramount importance.

On detailed questioning, the patient admitted that on November 21st she and her husband had eaten pork sausages without any apparent ill effects. On Thanksgiving day, November 27, she had eaten some pork sausages purchased in one of the neighborhood Italian stores; and on the following Sunday night the patient began to complain of a headache for the first time.

Physical examination at the time of admission revealed a well-developed, well-nourished, white female, about twenty-five years of age, who appeared acutely ill. There was marked edema of both upper and lower eyelids, the face was considerably swollen, and the back of her hands and ankles were also somewhat edematous. There was a moderate injection of the pharynx with slight reddening of both tonsils. There were several palpable, discrete anterior cervical glands. The spleen and liver were not palpable and no rose spots were seen. The kidneys could not be There was considerable costo-vertebral tenderness on both sides. The reflexes were normal. A pelvic examination disclosed no important findings.

Her temperature on admission varied from 102 in the morning, to 103-103.5 in the afternoon; her pulse was 95; and respirations 24. The blood

pressure was 100/60.

Urine sp. gr. 1022; trace of albumin, no sugar, no bile, no acetone, no diacetic acid. The microscopic examination showed an occasional white cell and no casts. Her non-protein-nitrogen was 30 mg. per 100 c.c. blood. Hemoglobin 92 per cent, red blood cells 4,890,000, white blood cells 13,200, of which 25 per cent were lymphocytes and 78 per cent polys.

Her temperature continued to fluctuate, her itching increased somewhat, and her edema subsided slightly; but she still continued to complain of a generalized headache. An opthalmoscopic examination was negative. Blood culture report was negative. Widal agglutination test for typhoid was negative. Daily examination of her urine failed to disclose any kidney pathology. Several days later she began to have clonic contractions of her leg muscles, and severe pain in the calves of her legs.

It was about four days after entry that we learned from her and her husband that, about three weeks previous to admission, they had both eaten pork. By this time the white blood cells showed a presence of 10 per cent eosinophiles. Two days later another white count showed 20 per cent eosinophiles; and a biopsy taken from the right gastrocnemius revealed encysted larvae within the muscle fibres with considerable lymphocytic infiltration between the individual fibres. Some of the larvae could be seen moving under the oil immersion lens. The diagnosis of trichiniasis was then evident.

The patient stayed in the hospital about three and one-half weeks, symptoms being treated as they arose. At the time of her discharge the patient had apparently fully recovered.

AN EVALUATION OF THE ARSPHENAMINES FOR GENERAL USE WITH SPECIAL REFERENCE TO SULPHARSPHENAMINE

By EARL D OSBORNE, MD, RAYMOND J RICKLOFF, MD, and MILTON G BUTLER, MD, BUFFALO, N Y

Read at the Annual Meeting of the Medical Society of the State of New York at Buffalo N Y, on May 25 1932

7 ITHIN the past few years there have been a number of excellent articles on the toxic effects of the various arsphenamines and their relative value in the treatment of syphilis In 1929, Moore¹ and his collaborators brought the existing information up to date in reprint No 13 of the United States Public Health Service Last year, Cole" and his associates summarized the existing knowledge up to that time and added their experiences in detail. Cannon and Karelitza reported last year on the comparative value of the arsphenamnes in the treatment of early syph ilis giving their results mostly from the standpoint of serologic and clinical response. In addition to these articles, Stokes' in his new section on syph ilis, in Tiees' Practice of Medicine has discussed the relative value of arsphenamine, neoarsphenamine, sulpharsphenamine silverarsphenamine and bismarsen. In view of all these excellent articles mentioned above, it would seem hardly indicated to present again an evaluation of the arsphenamines for general use were it not for the fact that the 1931 report of the Division of Social Hygiene of the New York State Department of Health showed five times more sulpharsphenamine dispensed to the physicians of New York State than regular arsphenamine The popularization of this drug among the general physicians of New York State we believe to be a serious mistake, in view of the data furnished in the articles above cited, and in view of the microchemical studies on rabbits which we made last year follow

ing the administration of arsphenamine, neoars phenamine and sulpharsphenamine in rabbits. In this paper, we will summarize the information contained in the above mentioned articles and, in addition, summarize our own reactions from the arsphenamines and, finally, discuss the chemistry and metabolism of the arsphenamines.

Reactions to the Arsphenamines

In Chart I, we have summarized, as far as possible, the experience of the investigators mentioned above in the frequency of the common reactions following the administration of arsplienamine, neoarsphenamine, and sulpharsphenamine. There are three outstanding facts illustrated in this chart

1 Early reactions such as the intritoid and gastro-intestinal reactions were about equally divided between neoarsphenamine and old arsphenamine. None of the authors mentioned the frequency of these reactions following sulphars phenamine.

2 Jaundice apparently was reported more frequently after neoarsphenamine than old arsphenamine, and here again sulpharsphenamine was not mentioned Cannon and Karelitz did not use sulpharsphenamine

3 The authors are of the unanimous opinion that the serious late complications of dermatitis, purpura, and hemorrhagic encephalitis have their highest incidence following the use of sulpharsphenamine. It is a striking fact that Cole and

CHART I
INCIDENCE OF REACTIONS AFTER VARIOUS ARSPHENAMINES

Type of Reaction	Moore et al	Cole et al	Cannon and Karelitz*	Stokes
Nitritoid	More common after neo	Same for neo and old araph	About the same after neo and old arsph	
Severe Gastro Intestinal Disturbance		Same	Same	
Jaundice		More frequent after neo	Slightly more com- mon after neo	
Dermatitis	Highest incidence after sulph	Same for neo and old arsph	More common after neo	More common after sulph Less often after neo
Purpura	Same	More common after sulph	No cases	More common after sulph
Hemorrhagic Encephalitis	Same	Same	No cases	Same

^{*}Authors did not report on the use of Sulpharsphenamine

his collaborators reported six cases of hemorrhagic encephalitis of which four followed the use of sulpharsphenamine, which drug was so little used in comparison to arsphenamine and neoarsphenamine.

Bearing in mind the above findings, we have recently reviewed all of the severe, late reactions occurring on our service at the Buffalo City Hospital during the past five years. Arsphenamine has been the drug of choice as a routine measure. Up to four years ago the usual dose was .1 gram for every thirty pounds of body weight. For the past four years our maximum dose of arsphenamine has never exceeded .4 grams in males and .3 grams in females in contrast to the former maximum of .6 and .5 grams in males and in females, respectively. Our acute reactions, including the gastro-intestinal reaction, have markedly diminished since reducing our maximum dose. The drug has always been diluted .1 gram to 25 cc. of water and each injection has required a minimum of one minute for each .1 gram of drug. We have never used neoarsphenamine in the treatment of clinic patients. Silverarsphenamine has been used in most patients presenting nitritoid and gastro-intestinal reactions. Sulpharsphenamine, subcutaneously or intramuscularly, has been used as a routine only in those patients presenting technical difficulties in the administration of arsphenamine intravenously and in all cases of congenital syphilis under the age of fourteen years. In all probability one of the reasons why we have not had more serious late reactions from sulpharsphenamine has been the fact that our maximum dose has been .4 grams in adults and .3 grams in children. Cole and his associates used .6 grams as a maximum and this dose is generally advised. Two grams of tryparsamide has been our maximum dosage in dispensary patients. In the case of arsphenamine and sulpharsphenamine we have given weekly treatments for an average number Silverarsphenamine has been adminof eight. istered every five to seven days for a total of eight to ten injections, per course. Tryparsamide is administered weekly in courses of from 20-40 injections.

In summarizing our results from the administration of these drugs, we include only those reactions occuring during the five year period from 1927-1931 inclusive. During this period there were administered 22,336 injections of arsphenamine, 3,584 injections of sulpharsphenamine, and 9,734 injections of tryparsamide. In the case of arsphenamine, all of the injections were given to adults, that is, in individuals past the age of 14 years, whereas with sulpharsphenamine, only left injections were given to adults and the rehad ter to children under the age of fourteen of the paration for purposes of comparison is following that because it is well recognized that plain of aldom react to any arsphenamine. This,

3 due to the relative efficiency of the

liver of a child as compared to the liver of an adult. Two years ago, Osborne and Putnam⁶ reported on the use of sulpharsphenamine in the treatment of congenital syphilis at the Children's Hospital in which report we had no reactions of a serious nature to sulpharsphenamine over a five year period. Since that time we have had two cases of mild dermatitis at the Children's Hospital and one at the Buffalo City Hospital. Chart II shows the number of late serious reactions to arsphenamine, sulpharsphenamine and tryparsamide in both adults and children. As will be noted there were two deaths from dermatitis following

arsphenamine. One of these deaths occurred in a pregnant woman who, in view of this fact, was grossly overtreated. It has always been our custom to reduce the dose of arsphenamine to onehalf or two-thirds the usual maximum after the fourth month of pregnancy. We wish to call special attention to the seven cases of jaundice following the use of tryparsamide, including one fatal case of acute yellow atrophy. The general opinion has been that tryparsamide causes little or no damage to the liver with the ordinary maximum dose of .2 or .3 grams. It has been recommended that as many as 60 or 100 or more tryparsamide injections be given without any intervals of rest. In view of our experience, this would seem to be a mistake and we would strongly recommend that tryparsamide be given in courses of not more than 20 injections each. This question will be discussed further in our consideration of the micro-chemical findings of the tissues of the rabbit following the administration of the drug

Chart III indicates the division of reactions among adults and children. All of the reactions following arsphenamine occurred in adults. Ten of the eleven reactions following sulpharsphenamine occurred in adults and one in a child, whereas approximately seventy-five per cent of all the sulpharsphenamine administered was to children. In Chart IV, the incidence of late reactions to arsphenamine, sulpharsphenamine, and tryparsa-

mide in adults is indicated. It is a striking fact that, following arsphenamine, the incidence of jaundice was 1 in 800 injections whereas, following sulpharsphenamine it was 1 in 179 injections. Dermatitis occurred with an incidence of 1 in 859 injections following arsphenamine whereas it oc-curred in 1 in 298 injections following sul-pharsphenamine. We had no cases of purpura following arsphenamine whereas, we had two following sulpharsphenamine. The incidence of jaundiee following tryparsamide was 1 in 1391 injections and there were no eases of dermatitis or purpura. The conclusions from these figures are obvious. In adults following sulpharsphenamine, the liability to jaundice is over four times as great as great as following arsphenamine and the liability to dermatitis is almost three times as great. The incidence of purpura following sulpharsphenamine from our figures and also in the literature, is vastly greater following sulpharsphenamine than after arsphenamine. We believe that the comparison would have been more odious had we used the usual maximum dose of .6 grams rather than the conservative maximum of .4 grams in the ease of sulpharsphedamine.

A Discussion of the Metabolism of the Arsphenamines and Tryparsamide

A clear understanding of the metabolism and chemistry of the various arsenicals would aid materially in the understanding of the various reacvalent, tryparsanude, has less effect upon the liver than the trivalent arsphenamine. We believe that the studies reported on last year by Osborne, Putnam and Hitchcock! on the effect of arsenic on rabbits explains a great many of the effects of the various arsenicals as used in the treatment of syphilis. Chart V is taken from this study. The following facts seem pertinent:

1. Following the administration of therapeutic or lethal doscs of arsphenamine, the liver takes up the drug, metabolizes it and passes it on to the organs of exerction, namely; kidneys, stomaeli, small intestine and colon. In the case of a therapeutie dose of arsphenamine, the liver handles it rapidly and it disappears rapidly from the organs of exerction. Twenty-four hours after a lethal dose of arsphenamine the liver contains maximum quantities of arsenie and very little has been passed on to the organs of exerction indicating that the liver was more or less overwhelmed by the drug. In the ease of ncoarsphenamine, the liver was able to metabolize and pass it on to the organs of excretion much more rapidly than following a Icthal dose of arsphenamine. With sulpharsphenamine, the liver was simply overwhelmed by the drug and was unable to pass on any arsenic to the organs of excretion, except in very small quantities. In the case of tryparsamide, there was no evidence of storage of arsenic iollowing the therapeutic use of this drug. However, following the injection of a lethal dose of

tryparsamide, the liver gradually took up more and more arsenic in proportion to the liver damage. In other words, it is evident that tryparsamide, administered to an individual with a previously damaged liver might end in disaster. More attention should therefore be given to the condition of the liver in individuals receiving tryparsamide therapy.

Therapeutic Efficiency of the Arsphenamines

We believe strongly that arsphenamine is approximately twice as efficient therapeutically as neoarsphenamine, when administered in equal doses. It is therefore necessary to give twice the dose of neoarsphenamine as required for arsphenamine to secure the same therapeutic result. Therefore the total amount of arsenic is actually greater when neoarsphenamine is administered. From a clinical standpoint, we have never seen, in our clinic, a recurring secondary syphilis following the proper use of arsphenamine combined with a heavy metal, whereas, in a period of five years, we saw over 20 recurrences following the use of neoarsphenamine by practicing physicians outside the institution. This is perhaps not a fair comparison because arsphenamine is not generally used by general physicians, but it is a striking fact nevertheless. Ease of administration is not a sufficiently justifiable excuse for using neoarsphenamine when arsphenamine is a more effective drug. In our experience, silver arsphenamine is an excellent drug and we prefer it in all cases in which arsphenamine cannot be used. There is no question but that sulpharsphenamine is an effective drug in the treatment of congeni-

tal syphilis because of its ease of administration. Since children metabolize the drug so readily on account of more efficient livers, it would seem that its continued used is indicated with a maximum dose of .1 gram to every thirty pounds of body weight. In adults, we feel that sulpharsphenamine is also effective therapeutically but that its use should be limited strictly to those individuals in which there is a technical difficulty in the administration of arsphenamine intravenously.

Conclusions

- 1. We prefer arsphenamine in the routine treatment of syphilis. From the standpoint of reactions and the therapeutic results it is superior to all others.
- 2. Silverarsphenamine is our second choice for all patients showing acute early reactions to arsphenamine such as the nitritoid and gastrointestinal reactions.
- 3. Sulpharsphenamine is a dangerous drug for general use. In adults it is four times as liable to produce jaundice and three times as liable to produce dermatitis as arsphenamine.
- 4. Sulpharsphenamine is more toxic to the liver than arsphenamine or neoarsphenamine and is therefore metabolized more slowly. The damming back of this vasculo-toxic drug in the blood stream is evidently the cause of the large number of vascular accidents.
- 5. Seven cases of jaundice including one case of acute yellow atrophy following tryparsamide are reported. Courses of not over twenty injections of tryparsamide in each series are recommended.

NOTES ON AVIAN TUBERCULOSIS OF THE SKIN*

By R H RULISON, MD, NEW YORK, N Y

THEN Robert Koch, before the Berlin Physiological Society (March 24, 1882), annonneed the discovery of the tubercle bacillus lie was able to report the presence of the germ in thirty cases of tuberculosis in human beings. Material had been obtained from eleven cases of inflary tuberculosis, twelve cases of cheesy broncho-pneumonia, one case of tubercle of the brain, as large as a hazel nut, and two cases of intestinal infection. In addition he had found the organism in two of the three specimens of scrofulous glands examined and in two of four cases of synovial degeneration of joints

Among the lower animals he had found the bacillus in thirteen cases in cattle, in a cheesy gland from a pig, a tubercular hen and in three monkeys which died of spontaneous tuberculosis I urthermore he had identified the germ after inoculation of 172 guinea pigs, 32 rabbits and five

He had grown the bacillus in pure culture from a large number of these cases and felt that they all represented the same organism

It so happened that he had not grown cultures from the tubercular hen and that he had not inoculated any birds with the tubercle bacillus

A wave of enthusiastic search for inicro organisms followed this discovery and all over the world bacteriology became a popular study Vetermarians took a prominent part in these researches and it was not long before doubt as to the identity of the human and the bovine types of tubercle bacillus was raised

A heated disagreement developed over this point and, later, as to the pathogenicity of the bovine strain for human beings. The quarrel was complicated by the fact that some of the French laboratories were using cultures grown by Nocard and Roux from a tubercular pheasant. This culture, of course, must have been the avian type Because of the resulting difference in laboratory findings the dispute became so violent that it is spoken of as "the great misunderstanding"

In 1890 Maffucci published a paper in which he said that, without taking up the quarrel as to the possible difference between the human and bovine forms of tubercle bacilli, he was prepared to show that the tuberculosis of birds was due to

a type distinct from either His work was so convincing that Koch, in the same year, accepted it and announced that an avian form existed and that the important question was, "Is it pathogenic for man ?"**

The laboratory differentiation of the liuman, bovine and avian strains is difficult. It is true that there are text-book differential points, but many atypical cultures occur which are extremely difficult to classify Lydia Rabinowitsch, a great expert, after studying one culture for a year, stated that while at first it semed to belong to the avian type she later became convinced that it represented an atypical bovine form

Another confusing feature lies in the discovery by Petroff that most pure cultures, when subsected to analysis by cultures from a single organisin, are found to consist of bacilli some of which grow with a rough and others with a smooth The smooth cultures seem to be more virulent than the rough and thus the virulence of any culture may depend on the proportions of the two kinds

To definitely classify a culture of tubercle bacilli both the cultural characteristics and the response of various laboratory animals to inoculation must be determined. Clinically there is a different response of various animals and birds to the different types of tubercle bacilli however, unsafe to venture a positive diagnosis of the type of tubercle bacillus causing a lesion on clinical or pathological examination alone organism must be recovered and identified by

laboratory methods

In practice, recovery of the tubercle bacillus is most easily accomplished by inoculating diseased material into animals, usually guinea-pigs the pig dies within a certain time an autopsy is done and cultures are taken in the hope of obtain ing a pure growth

It may be that this procedure has caused the failure to positively diagnose many cases of avian tuberculosis because the guinea pig is highly resistant to inoculation with the avian strain such cases the pig would remain in good health and the moculation would be recorded as having failed to cause tuberculosis Rabbits and birds

^{*} Real at the Annual Meeting of the Medical Society of the State of New York at Buffalo N Y, on May 24 1932

^{*}A fourth strain of tubercle bacillus was i lentified much more recently. This is the reptition or coll blooded strain. While it is sail to have been found in a lew cases in man it is n entioned here only to complete the group.

can be inoculated successfully with avian tuberculosis by the intravenous route.

Avian tuberculosis does occur in human beings but it is rare. Less than forty cases have been reported in the entire literature and a number of these are thought to be insufficiently proven. Branch is willing to accept only 14 cases.

It appears that human beings are highly resistant to this type. L'Esperance, after some experimental work in sensitizing guinea-pigs with killed human tubercle bacilli and later inoculating them successfully with avian, suggests that possibly men who develop avian tuberculosis have been previously sensitized by human or bovine infection.

Avian tuberculosis in human beings is, then, a rare occurrence and its diagnosis with certainty involves long and skillful laboratory work both cultural and by animal experimentation.

A diagnosis based on pathological findings alone is open to serious criticism. The histopathology of avian tuberculosis is usually different from that of human or bovine and the tissues most frequently involved vary from those attacked by the other strains, but enough atypical cases occur to make diagnosis by this means alone extremely hazardous.

In a suspected case it is desirable that Koch's postulates be strictly fulfilled and that the report of the case contain complete data as to the methods used to identify the causative organism. Very few of the reported cases fulfil these requirements.

Where complete proof is impossible it would be preferable to report the cases as probable rather than as proved avian tuberculosis.

A clear cut diagnosis is desirable because several cases have been arrested or improved by the therapeutic use of avian tuberculin. This successful therapy has been noted in three of the renal infections, one case having remained asymtomatic for over a decade.

Where avian tuberculosis is suspected the first step in diagnosis is the intradermal tuberculin test using both avian and human extracts. The reaction to the avian should be more positive than that to human.

In human beings various conditions have been diagnosed as due to avian infection. Skin and mucous membrane lesions were reported as occurring in 11 cases. The avian tubercle bacillus was recovered from seven of these cases after inoculation of tissue into chickens and in an eighth by means of a blood culture. The other three cases gave a highly positive intradermal reaction to avian tuberculin and were therefore suspected of being due to this organism.

In cases without skin lesions the avian type was recovered from the urine in five cases (indicating renal tuberculosis), from the spleen in four cases and from the lymph glands in four cases. Atypical tuberculosis of the liver and spleen, a

few cases of blood dyscrasias, abnormalities of the bone marrow and a fatal type of septicæmia have all been reported as caused by avian infection.

In four cases the organism has been recovered from sputum but three of these cases are not accepted and none have been reported during the past 25 years. Lung involvement seems to be a rare feature of avian infection.

To summarize it may be said that avian tuberculosis in human beings attacks the skin and mucous membranes, the kidneys, the spleen, the lymph glands, the bone marrow and sometimes causes a form of general sepsis.

Reported cases of aivan tuberculosis of the skin. Lipschutz, in 1914, reported the first of these cases.

The patient was a man 20 years of age who had had ulcerating lesions of the nose, upper lip and hard and soft palate for four years. The skin showed multiple, brownish-red, nodular infiltrations, slightly elevated, round and plateau-like with occasional ulceration. These lesions, aside from those on the face, were most marked on the hands, feet and elbows. The patient died of a tubercular septicæmia and at autopsy lesions were found in the bones, liver and upper small intestines. Miliary tuberculosis of the lungs was present. No diagnosis was reached during life but the avian tubercle bacillus was recovered post-mortem from material taken from the upper lip.

(2) Volk (1928) reported a case in a boy of 17 who had been employed on a chicken farm and had gone barefoot in the chicken yards. For several years he had had ulcerations of the left foot and leg. The lesions began as dermo-hypodermic nodules which softened and became ulcers of various sizes. The avian tubercle bacillus was recovered.

(3) Urbach (1928) reported a case occurring in a man aged 31. The illness was of 1½ years duration and began with fever and painful swelling over the sternum. Later ulcerations of the tongue, lips and the peno-scrotal angle developed. Still later painful swellings of the knees were noticed. The avian tubercle bacillus was

recovered from lip tissue.

(4) In 1929 Nicolau and Blumental diagnosed a case of avian tuberculosis of the skin occurring in a 19-year-old farmer. For five years he had non-ulcerating, raised, tuberculous lupus of the nose, forehead, lobule of the left ear, left side of the neck and back of the left hand. All lesions resembled ordinary lupus except the one on the ear, which in volume and gelatinous consistence suggested the variety called "lupus myxomateux." The avian tubercle bacillus was recovered from tissue excised from the ear and from the neck. The authors call attention to the fact that all previously reported cases were characterized by ulcerative lesions whereas theirs was one of non-ulcerating lupus.

Urbach (1929) in a beautifully illustrated paper again reports his case of aphthous and ulcerative lesions of the mouth and genitalia. He adds that there was a septic temperature, loss of weight, adenopathy in the cervical and axillary regions and, later, the development of herpetform lesions on the inner thighs near the scrotum with ulcerations and impetiginous eruption.

In the same paper Urbach reviews Volk's case and also reports (5) one belonging to Knossew which occurred in a hotel employee flus patient had abscesses of the leg and hlush-red papules with scarring which had been present over a long period. The avian tubercle bacillus was recov-

ered from pus from the abscesses

Urbach further speaks of two cases (6 and 7) of sarcoid of the face with infiltration and a bluish-red color. Histologically these cases were diagnosed as belonging to the Darier-Roussy type Both gave more intense reactions to intradermal avian tuberculin than to human. Neither case

yielded the avian bacillus Urbach reported another case (8) before the Vienna Dermatological Society May 8 1930 The patient was a man aged 49 Since 1917 lie had had night sweats, increased temperature and expectoration. Otitis media tuberculosa was pres-In 1926 a painless swelling of the inueous membrane of the cheek had developed testicular and prostatic tuberculosis appeared Finally tubercular infiltrations of the left vocal chord and of the posterior wall of the larying were noted. The patient had been in contact with cluckens during early adult life He gave a strongly postive reaction to avian tuberculin and Lowenstein recovered the avian organism from blood cultures

At this same meeting Löwenstein, during discussion of the last case, added another (9). He stated that a patient had recently come to autopsy from whom he had two years previously recovered the avian beeiligs. The recovery land been made both from the blood and from a tumor of the mucous membrane of the mouth

From this brief review of the literature of avian tuberculosis of the skin it appears that Urbach's suggestion that four types of lesions occur may need to be extended. Urbach thinks that there is, first, an aphthous form, usually accompanied by septicemia and bone and joint involvement. Second, a sarcoid like lesion third a guininatous form, and fourth a local illerating form. He considers the first three to be hemato genous in origin and the last due to direct inoculation.

The case reported by Nicolau and Blumental which Urbach seems to have overlooked does not fit into any of these groups for their case belonged chinically in the lupus classification

No case of definitely proved even tuberculosis of the skin has as yet been reported in America Two probable cases which I have studied may

ment brief mention. The first (10) is one of Hodgkin's disease with true Hodgkin's disease of the skin, occurring in a married woman aged 38. The condition had been present 6 months. The histologie diagnosis was made from an axillary gland and from skin taken from the cheek. Both specimens were diagnosed Hodgkin's disease by Dr. L'Esperance. Flic patient gave a strongly positive reaction to avian tuberculin and a much less marked reaction to human tuberculin. She improved after one course of Rontgen ray treatment followed by increasing doses of avian tuberculin continued for over a year.

All treatment was discontinued in May, 1930, and the patient was considered in excellent con-

dition

In the winter of 1930 31 she became ill after exposure to cold and died in February of this year with extensive lung involvement. No autopsy could be obtained

The skin lesions in this case were very interest-They entirely disappeared during treatment ıng and did not recur during the last illness There was a diffuse, dusky, erythema occurring in irregular patches involving parts of both ears, the temporal regions and the cliceks in front of the A separate, lima bean sized lesion was present near the left angle of the mouth which the patient said had at first been somewhat raised and hard but which at the time of examination, was macular and showed no increased infiltra-Efforts to recover the avian tubercle bacillus from chickens inoculated with gland material The very positive reaction to avian tuberculin and the improvement following its long continued therapciitic use are the only evidence that this patient had avian tuberculosis

It should be mentioned here that Dr L'Esperance has recovered the avian bacillus from three cases of typical Hodgkin's disease and from one of the Pel Ebstein type of this disease. Her findings in the latter case have been checked and accepted by Branch and his collaborators at Harvard as a proved case of avian tuberculosis.

(11) The second case is one clinically diag nosed lipus erythematosus of the face scalp and nucous membranes of the mouth. The patient was a female whose skin lesions first appeared seven years ago at the age of 21. She had had tubercular cervical adenitis five years previously. The nose and adjacent cheeks were involved as well as a patch on the right side of the scalp the right malai eminence, the lips and the liard palate, on which ulcerations were present. The eruption was at first quite superficial but later became rather deeper than is usual in this condition and marked crusting and scaling appeared.

The patient thought that this change did not occur until she had had some treatment with gold and sodium thosulphite. Focal infection had been sought and removed and the patient had been treated with gold for ibout two years with

out improvement. She came to Cornell Clinic in November, 1929, to ask if any other method of treatment could be suggested.

She reacted very strongly to avian tuberculin and gave only a plus minus reaction to human

tuberculin.

Efforts to recover the avian bacillus failed re-An excised cervical gland showed tubercle bacilli in sections but no success followed inoculation experiments. Repeated examinations of urine were negative. Finally the scalp lesion was excised and an emulsion injected into a chicken. The chicken died in 15 days and cultures eventually proved to be avian tubercle A rabbit inoculated intravenously with this culutre died in 15 days with evidence of tuberculosis.

The patient was treated for nearly two years with avian tuberculin. Considerable improvement occurred. However, this never reached a point where the condition could be considered cured and finally no further progress could be noticed.

Although Dr. L'Esperance has positively identified the organism recovered from this case as the avian type there are certain gaps in the laboratory evidence, and I do not wish to claim that Koch's postulates have been entirely fulfilled in this case. The original culture from the chicken was contaminated by a mould and a long time elapsed before a pure culture could be obtained. Because of this unavoidable delay certain animal inoculations have not been done and adequate control reports are not available.

However, the patient did react strongly to avian tuberculin, did improve under avian tuberculin therapy and the avian organism was recovered from a chicken inoculated with scalp tissue. The case is reported as one of probable avian tuberculosis of the skin.

Avian tuberculin therapy continued over a long time was accompanied by clinical improvement in both these cases. In neither case was a cure obtained.

SUMMARY

Avian tuberculosis is a rare occurrence in human beings. The tissues most commonly affected are the skin, the lymph glands, the kidneys, the spleen and the bone marrow. In addition a septicæmic form has been reported.

Eleven cases with skin lesion have been reported. In several of these the diagnosis is in-

complete.

Skin manifestations have been reported having (1) an aphthous, ulcerating, septicæmic form, usually with bone and joint involvement; (2) a gummatous form; (3) a lupus form; (4) a local ulcerating form, and (5) sarcoid-like lesions. One case of Hodgkin's disease of the skin may possibly have been due to avian bacilli.

In chronic skin lesions, where diagnosis has been impossible it might be advantageous to use intracutaneous tuberculin tests. A strongly positive reaction to avian tuberculin as compared with human and bovine would suggest further investigation. Inoculation of chickens with emulsified tissue should be done, since guinea-pigs are resistant to avian inoculation.

Discussion: By Dr. Louis Tulipan, New York, N. Y .: The study of Avian Tuberculosis in human beings is a difficult one and its possible association with Hodgkin's Disease requires fur-

ther study on a larger series of cases.

The fact that acid-fast bacilli have not been isolated from the glands of Hodgkin's Disease directly, but only indirectly, by the injection of ground-up Hodgkin's glands into birds, is not positive proof that Hodgkin's Disease is an atypical form of tuberculosis due to the avian tubercle

The difficulty encountered in this type of work is, that there is no infallible way of diagnosing tuberculosis in birds, inasmuch as the tuberculin test may be negative. Another possibility of error, is that of spontaneous infection from other birds or the ground, where the experimental birds are kept.

MEDICAL ECONOMICS

There must necessarily be an economic element in the relations of practicing physicians to their patients. This element is undergoing a process of development and evolution. No longer does public sentiment impose on the medical profession the entire burden of giving medical care to the poor; and physicians are learning that the free services which they render in clinics belittles rather than enhances their professional reputation.

Medical societies are making extensive studies of the medical needs of their communities and the means of supplying them. Social organizations are developing plans by which communities shall provide medical service to the poor on a basis similar to that used in giving them food and shelter. The dollar is universally accepted as a standard of value in the distribution of all kinds of service, including that of medicine.

SWALLOWING SAFETY PINS

Resourcefulness is an essential qualification of a practitioner of medicine, especially a surgeon. The resourceful surgeon deserves credit for a procedure that is original with him, although some one had used the same solution before.

Priority of discovery is ascribed to him who first publishes his observation; and those doing equally original work do not obtain recognition because they fail to report their observations. Modesty is commendable and restriction of medical literature of a commonplace type is desirable; but every medical editor is delighted when an observation which is both original and practical is offered to his journal. Such an observation is found in the May issue of *Minnesota Medicine*, the Journal of the State Medical Association, which carries a brief article on "The Open Safety Pin in the Digestive Tract," by Dr. George Earle of St. Paul.

Dr. Earle was called on October 12, 1932 to see a ten months' old baby who had swallowed an open safety pin two days previously. The x-ray showed the progress of the pin, butt first, down the esophagus, but it evidently turned in the stomach and lodged point first in the pylorus. A laparotomy was done on the sixth day, but instead of opening the stomach, the surgeon gently manipulated the pin back into the stomach and closed it, and then left it free in the stomach. The pin was expelled from the body on the eleventh day after it had been swallowed.

The article goes on to say:—

"Dr. Greth Gardiner, consulating endoscopist, had suggested in the event of a subsequent

laparotomy that the pin be closed through the bowel wall and left to pass, thus greatly decreasing the possibility of an operative death. Children of this age are known not to tolerate opening of the bowel, and while there is probably less risk in opening the stomach than the duodenum, the risk should be avoided if possible.

"At the time of the operation, as far as Dr. Gardiner knew, the suggestion of closing the pin and allowing it to be passed was independent thinking. Dr. Gardiner had made an extensive search of the literature three years previous, and at that time such a procedure had not been suggested. His search of the literature had followed a peritonitis death from the removal of a safety pin in the bowel, and at that time the thought had come to him that it would have been better just to have closed the pin and let it pass in the natural way. This case, in which he was called in consultation while the pin was in the esophagus, offered the first opportunity to make the suggestion."

The article quotes the Journal of the American Medical Association of March 11, 1933, page 736, describing the closure of an open safety pin which had been swallowed, and its removal by means of a stomach tube into which it was manipulated. This occurred twelve days before the operation described in Minnesota Medicine.

The Minnesota article quotes a newspaper report that on April 4, 1933, a Chicago doctor had closed an open safety pin in a baby's stomach, and that the pin had been recovered when the baby vomited.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Economics: This Journal of June 1908 quotes an editorial in the Texas State Journal of Medicine as follows:

"The average man will give a lawyer \$300 to \$500, together with a lifetime's praise, to keep him out of the penitentiary for from two to ten years, and at the same time he will raise a phosphorescent glow and kick that can be heard around the world if a doctor charges him \$50 to \$100 to keep him out of hell for a lifetime. We are the only people under God's ethereal tent today who keep open shop 24 hours each day and 365 days in each year. We are also the only laborers to keep on working for people who do not pay. I can carry my part of charity with as good a grace as most men. I can go through rain, snow or mud and

do my best, provided the case is one of worthy need, but to reward continually downright rascality, willful drunkenness and wanton laziness is getting out of my line."

"The average doctor tries to do much work. Every doctor wants everybody to patronize him. He likes to be going day and night, rain or shine, Sunday or weekday, hot or cold. This is a business mistake. It wears a doctor to a frazzle. It gives him no time for bill-collecting and business matters; no time for patients who naturally feel neglected and are slow pay as a consequence. A doctor can do better work, more good and build up a more enviable reputation if he coolly takes his time and is careful and painstaking in his examinations."

MEDICAL PROGRESS

Treatment of Neuralgia and Tumors by "Cobra Venom."-A report is made by Monaelesser and Ch. Taguet in the Bulletin de l'Académic de Médecine of March 14, 1933, of the results observed in 115 cases of tumors treated during the course of 21/2 years by injections of snake venom: chiefly that of the cobra, but in a few cases that of the rattlesnake. The purpose of the treatment was the relief of the neuralgic pains that accompany the growth of tumors. The neoplasms, mostly malignant, were in the most various locations, and included 25 of the mammary gland, 20 of the uterus, 15 of the intestine and rectum, 15 of the stomach, 10 of the prostate, 5 of the tongue, etc. A 1:80,000 solution of venom, prepared by Calmette's method, was injected in gradually increasing dosage based upon the mouse-unit, that is, the minimum dose toxic for a mouse weighing 20 gm. At the present time the authors administer at each injection 1/2 e.c. of a glycerited solution containing 21/2-5-10-15-20 or more mouse units, giving the injections at intervals of 3-5-10 or 15 days. An ordinary syringe is used with a short needle, and the injection is made into the cellular tissues, such as the supraspinate fossa of the deltoid region, the gluteal region, or the thigh. In weak dosage it is painless; larger doses cause a biting sensation for a few seconds, in rare cases for a few hours, but never any erythema, suppuration or any general febrile reaction. The treatment is entirely compatible with tonic or radiotherapeutic treatment, but its action is inhilbited by vaccines and iodated medication. The cases treated were unselected, and included grave cases, recently or long since operated on, with or without recurrence, inoperable cases, those unsuccessfully irradiated, and both external and internal cancers. The majority have died from their advanced cachesia, but in nearly every case the pain had been relieved. In some cases the tumor growth itself showed a stabilization for several months, and in a few, regression or even complete cicatrization has been observed. Some of the patients who received their first injections in October, 1930, are still under treatment. An analysis of the clinical observations reveals that the effects upon the pain first become evident after the fourth or fifth injection, when the acuteness of the paroxysms begins to abate. Cases in which the effects were very striking were a cancer of the tongue, a secondary mammary cancer following operations on adnexal and gastric tumors, a metastatic cancer of the first lumbar vertebra, a cancer of the cardia, and one of the uterus and adnexa. On the other hand, cases with advanced lesions of the bladder, rectum, body of the uterus and certain tumors of the pylorus, liver and pancreas proved entirely refractory.

Magnesium Sulphate in the Treatment of Angiospasm. - N. Pines, writing The Lancet, March 18, 1933, cexxiv, relates his experience with magnesium sulphate in intermittent elaudication, spasm of the brachial artery, migraine, acute pulmonary edema, angina pectoris and coronary thrombosis, and cerebral angiospasm. Angiospasm, he says, may affect any part of the arterial tree. The duration of a vascular spasm may be a few minutes or a few hours, but the injury done may be immense if a portion of a vital organ is affected and is unable to recuperate quickly. Therefore medication must also be rapid and, of course, harmless. Recalling the efforts made to cure tetanus by subeutaneous or intratheeal injections of magnesium sulphate, Pines decided to try it in vascular spasm. After considerable experimentation it was found that the intravenous mode of administration was preferable, but if for some reason this route is impracticable, the solution of magnesium sulphate (without glucose) is well tolerated intramuscularly. For intravenous injection the dose is 5 to 10 e.c. of a 20 per cent solution of magnesium sulphate and an equal volume of 10 to 40 per cent glucose. About a minute and a half after the commencement of the injection the patient feels an intense heat in the body. The pulse becomes moderately quickened. The blood pressure is unaltered. On ophthalmoscopic examination the retinal vessels show no change. The magnesium sulphate probably relaxes vascular spasm by direct action on the vasomotor center of the brain (either cerebral only or spinal as well). No discomfort was experienced by any of the patients, though some of them were well over sixty years of age, and no harm has resulted from the injections even in cases of cerebral "vascular aceidents"; sometimes a striking improvement seemed to follow. Usually the treatment was administered twice a week.

Aspergillus as a Cause of Blindness.—Marg. Rohner and Oth. Huber say that few cases of disease of the vitreous due to invasion of hyphomycetes have been published. That hyphomycetes should cryptogenetically reach the vitreous body and cause blindness is one of the rarest of occurrences. Cases in which this fungus has attacked the cornea are, on the contrary, not very unusual. The epi-

thelium is destroyed, an ulcer forms, which is surrounded by a yellow ring of leucocytes, constituting the demarcation wall, which as a rule hinders further proliferation of the fungus. In rare cases, however, the fungi may make their way from the cornea into the anterior chamber and thence pass into the vitreous body. When this occurs a panophthalmia follows. Most of the cases reported of hyphomycetic invasion of the cornea have been due to aspergillus, and especially to The most interesting feature of A. fumigatus. the authors' case is that the hyphomycetes were found in the vitreous without there being any indication, either clinical or histological, as to the route by which they arrived there. The patient, a man of 41, reported that 3 days previous to observation he had noticed black spots in front of the right eye, and a striking decrease of visual acuity, with transient pain. As the eye was somewhhat reddened, he had applied compresses of bread and fresh butter. It is perhaps significant that none of the bread had been over 3 days old. The anamnesis also showed that the patient had often had a kind of eruption on his eyelids and on the extensor side of his elbows. Two months before, a cow had kicked him in the nose, but the eye had not suffered. Upon slit lamp examination the cornea and sclera were found perfectly in-The anterior chamber was full of a grayish white flocculent exudate, making it impossible to get a view of the vitreous and fundus. During several weeks of treatment condition grew gradually worse, until finally all vision was lost, and the eye was enucleated. Histological examination vealed no sign of any cicatrix in the cornea or The corneal epithelium, the parenchyma, Descemet's membrane, and the endothelium were all intact. The retina was almost entirely detached, and was seen lying in broad folds in the anterior portion of the vitreous, which had shrunk till it occupied but a small space. In the midst of the abscess lay a small collection of branched hyphomycetes, spreading more or less from a single point. No culture was possible, since the eye had been placed in formol, but it is highly probable that the fungus was the ubiquitous Aspergillus fumigatus, whose pathogenicity for the human eye is well known. It was impossible to guess how it reached the eye, and especially the vitreous. The presence of an endogenous infection cannot be altogether excluded. Schweiserische medizinische Wochenschrift, February 25, 1933.

Changes in the Character of Diseases.—Sir Humphrey Rolleston, writing in the *British Medical Journal*, March 25, 1933, i, describes changes which have taken place in the charac-

ter of certain diseases. He points out that Sydenham, the British Hippocrates, maintained that diseases had seasonal variations, a long period of evolution with a rise, decline, and fall extending over centuries, and an "epidemic constitution," namely, that they were subject to telluric or cosmic influences. On the other hand, that the character of acute ·diseases undergoes changes has been vigorously contested. It has been claimed that the supposed change was due to failure to recognize that a disease other than that supposed to have altered its character had appeared on the scene. Again it has been argued that improved diagnosis must be taken into account before accepting a supposed change of type in disease. At the present time no one can doubt the evidence of change of character in some acute diseases such as scarlet fever and smallpox. In order to realize the high probability that diseases must change their character it is only necessary to remember that they are not rigid entities. A morbid state is the outcome of two variables: the resistance or susceptibility of the body on the one hand and the numerous factors coming under the head of environment on the other hand. The influence of constitution is seen in hereditary and racial liability to certain diseases, for example, the frequency of diabetes in the Jews. The external environment includes microorganisms, poisons, physical agencies, trauma, unhealthy surroundings, tainted food, poverty, and over-fatigue of the body and mind. Moreover, bacteria must be more prone to mutations and changes in virulence than is man to develop changes in resistance.

In the European war there appeared new forms of disease—an increase in deficiency diseases, and a fall in the incidence of those due to dietetic excesses. The greater speed of modern life may be correlated with the increased incidence in Europe and America of epidemic diseases of the central nervous system. High blood pressure, cardio-renal disease, and diabetes may also be products of the strenuous existence. Improved hygiene has banished many acute infections, such cholera, typhus, and relapsing fever. Chlorosis has practically disappeared since the beginning of this century, and with it gastrostaxis and perforating gastric ulcer in chlorotic young women. Its place seems to have been taken by the simple achlorhydric anemia in middle-aged women. Acute rheumatism has, during the past eighty years, undergone considerable modification; its complication by pneumonia had disappeared fifty years ago. More recently there is a lessened severity of the arthritis affection. Tophaceous gout has been growing rarer. Syphilis is less obviously

mulignant than formerly, while syplithme aortitis has become increasingly common. Rolleston has the inspression that thoracic ancurysm has become less common than it was earlier in this century. Appendicitis has been much commoner since the return of influenza in 1889 after being absent for forty years. Cirrhosis of the liver is less frequent than formerly. Pneumonia has undergone a change since influenza again became prevalent, the frank lobar pneumonia is less frequent, while bronchopneumonia is more in evidence. Primary carcinoma of the lung has become much less rare since 1918. Hydatid disease has become quite infrequent within recent years.

Mixed Anesthesia for Long and Severe Operations in Deficient (Anemic and Obese, Subjects -In the opinion of Victor Panchet and A Hirchberg inixed anesthesia has made remarkable forward strides, due to the introduction of certain recent procedures, such as the preoperative sedative injection, the use of eserine, of carbon dioxide gas, and, most of all, of intermittent narcosis, the technique of which should be more widely known, for the welfare of the patients. At the outset, the preliminary injection of morphine, with or without scopolamine, followed by infiltration of the line of incision with a weak solution of percuine produces a state of calm which facili tates all forms of anesthesia. The oculocardiac reflex should be tested, if compression of the cyeball considerably accelerates the pulse, equilibrium should be re established by injecting ½ mg eserine salicylate when anes thesia commences This is especially useful in laparotomies Inhalation of carbon dioxide, either pure or mixed with an anesthetic, facili tates the arrival of ancethesia, the patient falling asleep more readily after the respiratory stimulation caused by a few whifts Periods of apnea are suppressed, the color remains healthy, and the respiration is full and deep Given again toward the close of anesthesia carbon dioxide promotes a more rapid elimination of the anesthetic The hyperventilation thus obtained also tends to reduce the number of pulmonary complications order to produce satisfactory narcosis the patient must be put to sleep slowly eliminates almost entirely the troublesome period of excitation observed when anesthesia is produced too rapidly Before operation is begun the patient must be brought into a sleep so deep that the eyeball becomes immobile the pupils contracted and the palpebral reflex abolished The Ombredanne mask is maintained at 6 or 7 while the surgeon is making the intraabdominal exploration. In practice this stage is short 5.10 minutes or at most a quarter of an hour. If the patient begins to exhibit intestinal contractions, the mask is promptly reapplied. As soon as exploration is ended and respirations are regular and deep, the mask is lifted and the patient allowed to breathe freely 5 10 minutes The mask is then replaced for I or 11/2 minutes at most, which gives the patient time for 20 30 slightly accelerated respirations, after which he may again breathe freely for 5 10 minutes In this way long, difficult and involved opera tions can be done without danger and with a minimum amount of anesthetic nignity of narcosis thus carried out has been especially striking in the case of obese sub jects with poor powers of resistance. A more than ordinarily easy anesthesia was conducted in two patients of this type whose cases are outlined, one markedly anemic, undergoing a sigmoid resection, and the other with an exaggeratedly brouzed skin covered with great numbers of nevi on whom an extensive right colectomy was performed -Bulletin de l'Academie de Medecine, March 21, 1933

A Study of the Sinuses in a Group of Patients Complaining of Vague Chest Symptoms -In order to obtain some idea of the relation ship between cliest symptoms and sinusitis when the latter has been ignored by the patient and physician Sam H Sanders examined the sinuses of a large number of patients in whom the diagnosis of chronic bronchitis had been made by one or more physicians The group did not include those who attached their primary symptoms to the sinuses or had a diagnosis of sinusitis before they were referred to the specialist. All were negative for tuberculosis. In this group of pa tients the statement is borne out that an upper respiratory infection is present in practically all cases of chronic non tuberculous pulmonary disease In some of these patients the physical findings in the nose were indefinite. One might be justified in passing the nose up as normal were it not known that the patient had a chronic pul monary lesion and a history suggestive of sinusitis Roentgenological examination of the sinuses in such cases will show a polypoid degeneration of the antral mucosa of varying degrees with some involvement of one or more of the other In some patients who complain or cough, headache, mucoid discharge from the nose, and continuous colds, the roentgenograms of the sinuses appear almost normal unless the picture is light with good contrast, and then a thickening of the mucous membrane can be seen. Some of these patients are treated for tuberculosis. The chest condition grows progressively worse unless the source of infection in the sinuses is removed Sanders urges the importance of early diagnosis and treatment of sinus disease before lower res piratory changes occur He hopes to see the day when the family physician will apologize for permitting a patient to reach the stage of bronchiectasis without a search for a definite upper respiratory infection, unless the evidence of the cause is elsewhere.—Southern Medical Journal, May, 1933, xxvi, 5.

A Case of Iodine Graves' Disease Following Bronchography.—A warning is uttered by T. Gordonoff in the Schweizerische medizinische Wochenschrift of March 11, 1933, with regard to the use of lipiodol or iodipin in bronchography in patients who for one or another reason exhibit an intolerance for iodine. There is very little understanding as yet of the fate of iodine in the body after bronchography, some authors holding that after a certain percentage has been coughed out, the residue lies in the alveoli for weeks or months, where it gradually becomes resorbed, while others take the view that the resorptive capacity of the lungs is but slight: that the lipiodol or iodipin can be resorbed only from the alimentary canal, and that on this account care should be taken that the expectorations are not swallowed. Gordonoff reports the case of a woman of 54 in whom an iodine Graves' disease developed after a bronchography designed to demonstrate bronchiectasia in the right lower lobe. The injection was followed by loss of sleep, tremor of the hands, excessive sweating, rapid pulse, loss of weight, and a lymphocytosis of 34 per cent in presence of 6,700 leucocytes per cubic millimeter. A control roentgenogram taken 1 month after the injection clearly revealed the presence of lipiodol in the right lower lobe. The basal metabolism could not be determined, but the diagnosis of Graves' disease could readily be made on the basis of the symptomatology and the roentgen To prove that lipiodol is resorbed in the lung, Gordonoff injected 2 c.c. of the substance into the trachea of a rabbit. hours he found 0.295 mg. iodine in the blood and 4.56 mg. in the urine; after 4 days there was 0.475 mg. in the blood and 5.71 mg. in the urine, while the removed lung contained 693 mg. iodine. The iodine wanders into the organism through the alveoli, where it finds no other way of exit, since the alveoli have no ciliated epithelium, and since, according to Rohrer, coughing has no effect upon them. Resorption is rapid in a healthy lung, but much slower in a diseased one, especially when the bronchi, as the result of dilatation, have a modified or thickened mucosa. In cases of hyperthyroidism, kidney disturbances, iodine idiosyncrasy, even small amounts of iodine resorbed are enough to produce injury. The author points out the necessity before every bronchography of examining not only the kidneys but also the gaseous exchanges with reference to a possible overfunctioning of the thyroid. Intracutaneous injections of minute amounts of iodine will bring to light any oversensitivity to the substance. Physicians are urged also after every

bronchography to order expectorants having secretomotor properties. Ether administered subcutaneously quickly dissolves the lipiodol in the lungs. It might be worth while to try it in combination with powerful diuretics in a case with sound kidneys, bearing in mind, however, that the resorbability of the iodine will be increased thereby. It would be still better in cases known to be intolerant of iodine to make use of a brominized opaque fluid.

Diabetes Mellitus and Postencephalitic Parkinsonism.—The possibility of the existence of a true neurogenous diabetes is discussed by Giuseppe Ceroni in the Riforma medica of February 4, 1933, on the basis of a case in a young man, in whom diabetes mellitus was associated with a syndrome of postencephalitic parkinsonism, which had begun to develop 3 years after an attack of epidemic encephalitis in 1922. The diabetes in all probability first made its appearance 7 years later, increased progressively for 2 years, then slowly regressed up to the present time. The state of hypertonia exhibited a course parallel to the gravity of the diabetes. That the condition was true diabetes was demonstrated by the constant glycosuria and hyperglycemia, and the response of the blood sugar to administration of glucose. Ceroni thinks the progress of the encephalitic lesions was the result rather of the intercurrent flaring up of the encephalitic inflammatory process than of secondary degeneration, and that the subsequent appearance of a diabetic condition was due to participation of the hypothalamic center that regulates sugar metabolism. Also the glycosuria, hyperglycemia and excess of sugar in the cerebrospinal fluid observed in the acute phase of epidemic encephalitis can be explained by assuming temporary disturbances of the paraventricular nucleus to which is assigned the control of sugar metabolism, just as the polyuria of the same disease is explained by dysfunction of the center regulating the water and salt metabolism. The patient had shown himself to be insulin-resistant in 1930-31, both the diabetic and the parkinsonian symptoms being increased during the treatment; but a more recent test has revealed a rather surprising sensitivity to insulin, not only the sugar excess but also the tremors and asthenia being markedly diminished under the treatment. This behavior certainly indicates a slight but manifest participation of the islands of the pancreas, which appears to have been secondary. It is probable that the primary lesion was at the level of the diencephalic center, and that in that period, when the pancreas was unimpaired, the insulin, instead of having the effect of decreasing blood sugar, stimulated the antagonistic neurohormonic sector. The idea of the primary nervous origin of this form of diabetes is strengthened by the long course not usually observed.

LEGAL

THE VASKO CASE

By LORENZ] BROSNAN, ESQ

Counsel Med cat Sociely of the State of New York

Several weeks ago a case came before one of the Appellate Courts of this State which received wide publicity and comment in the public press This matter, known as the Vasko case, presents a situation that cannot fail to be of interest to every doctor because of the human, as well as the medical situation involved. It is appropriate that the matter be discussed in these columns at some length

It had been ascertained at a certain hospital that a two-year-old infant child, the daughter of first generation immigrant parents, was suffering from ghoma of the return of the left eye, and the removal of the eye had been recommended in an effort to save the life of the child The parents, however, arbitrarily refused to permit the operation, flatly taking the stand that there would be no surgery performed even though the child A petition was presented by the County Society for the Prevention of Cruelty to Children, to the local Children's Court for an order requiring an operation to be performed upon the infant

The statute under which the proceeding was brought defines a neglected child to be protected under the Aet as one "whose parent, guardian or custodian neglects or refuses, when able to do so to provide necessary medical, surgical, institu-tional or hospital cire for such child" The Act further provides

'Whenever a child within the jurisdiction of the court and under the provisions of this Act appears to the court to be in need of medical or surgical care or therapeutie treatment, hospital care necessary appliances and de vices or of special educational training * * * a suitable order may be made for the treatment or education or both of such child in its home a hospital or other suit able institution and the expenses thereof, when approved by the court and duly audited shall be a charge upon the county or the proper subdivision thereof but the court may adjudge that the person or persons charged with the hability under the laws to support such child shall pay a part or all of such expenses as provided in section forty of this Act"

In response to the petition, the parents appeared before the Children's Court. The Court interro gated them and learned that the only treatment they would permit for the child was the application to the eye of some medicine obtained by mail from a so called "eye drops and herb specialist" who was not a physician The court directed the appointment of a physician of high standing to make an examination of the child and also ap

pointed one of the members of the Bar to represent the child and her parents in the matter

The examination was made and a week later the doctor appeared in Court and gave his opinion with respect to the need for operative interference in the case Part of his testimony was as follows

Q Will you please tell us the nature of the examina tion and what results or conclusions you arrived at?

A The external appearance of the eye is normal ex cept for one thing that is you see the reflects, red re flects from a light in front of the eye showing through the pupil. The pupil is widely dilated also and the eye is permanently blind. In looking into the eye there is evidence in the back part of the eye of a growth which has pushed it forward. It is detached and there is a new growth in the posterior part of the eye ball. There are numerous folds and you can see the blood vessels running through it. That growth in all probability is of a milignant nature which if left to nature will sooner or later cause the death of the child

Q How will the death of the child be caused by that

Doctor?

A The growth will increase in size until its fills the orbit until it fills the eye ball bursting through the coats of the eye ball fills the entire organ and pro-trudes out between the hids and also it will if left to nature in all probability go backward into the brain and follow up along the optic nerve into the brain, and by the same process in that locality

Q It is in the nature tumorous?

It is a tumor Q Can you state whether or not in your opinion with reasonable certainty what is necessary to be done in order to prevent the further growth and the probable fatal outcome of it?

A It is necessary to remove the eye and as much of

the optic nerve as it is possible to remove

Q Can you state whether or not in your opinion with reasonable certainty the child would die as the result of this malignant growth unless the eye is removed?

There is no question about it there is no doubt the

child will die of it

Q Just one more question. If the eye is removed at this time can you state whether or not in your opinion with resonable certainty the progress of the malignant growth will be arrested and the death of the child pre-

A There is something like an even chance One can not say with certainty the growth can be arrested my personal belief that the child has an excellent chance of living on if the eye is removed. Statistics show a cure in something like fifty per cent of these cases

The doctor also gave the opinion that the eye drops that the parents were using would have no effect whatever toward curing the child's condi-To summarize the matter, he testified that there was no chance at all of saving the child's life without operation

The services of a clergyman in the parish of the parents were enlisted by the court, but he too was unsuccessful in convincing the parents that the child should be operated upon.

An order was then made adjudging the infant to be a neglected child, reciting that the child was in need of medical or surgical care and would die unless the eye was removed. The order further directed the child to be committed to the custody of the Commissioner of Public Welfare, and by him placed in a designated hospital to be operated on by the doctor who had previously examined the child.

In order that the rights of the parents and the child might be given all possible consideration, an appeal was taken by the attorney who had been designated to represent the parents and who had also been appointed guardian ad litem of the child. The appeal was brought on very promptly for consideration before the Appellate Division of the Supreme Court for the Second Judicial Department, and briefs were submitted. No reported case was cited to the court in which the validity of a similar order had been challenged, and the propriety of the order was tested out by a determination of the scope and constitutionality of the statute as applied to the case.

One of the chief cases brought to the attention of the Appellate Court as tending to support the order, was a case that had been decided by the Court of Appeals in 1903. That case involved a conviction of the parent of a child, for a mis-demeanor under what is now part of Section 482 of the Penal Law. Said Section provides that a person is guilty of a misdemeanor who "Wilfully omits, without lawful excuse, to perform a duty by law imposed upon him to furnish food, clothing, shelter or medical attendance to a minor or to make such payment toward its maintenance as may have been required by the order of a court or magistrate when such minor has been committed to an institution." A parent had in that case failed to provide medical care for a sixteen and a half months old child who had contracted catarrhal pneumonia, although he realized for forty-eight hours before her death the serious condition of the child. In that case conviction was affirmed and the Court said:

"The peace and safety of the state involves the protection of the lives and health of its children, as well as the obedience to its laws. Full and free enjoyment of religious profession and worship is guaranteed, but acts which are not worship are not. A person cannot, under the guise of religious belief, practice polygamy and still be protected from our statutes constituting the crime of bigamy. He cannot, under the belief or profession of belief that he should be relieved from the care of children, be excused from punishment for slaying those who have been born to him. Children when born into the world are utterly helpless, having neither the power to care for, protect or maintain themselves. They are exposed to all the ills to which flesh is heir, and require careful nursing, and at times, when danger is present, the help of an experienced physician. But the law of nature, as well as the common law, devolves upon the parents the duty of caring for their young in sickness and in health, and of doing whatever may be necessary

for their care, maintenance and prescrvation, including medical attendance if necessary, and an omission to do this is a public wrong which the state, under its police powers, may prevent. The legislature is the sovereign power of the state. It may enact laws for the maintenance of order by prescribing a punishment for those who transgress. While it has no power to deprive persons of life, liberty or property without due process of law, it may, in case of the commission of acts which are public wrongs or which are destructive of private rights, specify that for which the punishment shall be death, imprisonment or the forfeiture of property."

It was argued that under the authority of the said case there would be unquestioned authority to take proceedings to punish the Vasko parents if the child were to die without medical care, and it would follow that with the power conferred by the Legislature by the Children's Court Act, the Court was justified in stepping in and attempting to prevent the tragedy.

The Appellate Division without delay handed down a decision affirming the order of the Children's Court. The opinion of the Court stated in part:

"This appeal presents, primarily, the right of the State, in a proper case, to assume the discharge of duties of parents or guardians in matters involving the life, health and physical welfare of their children or wards when it appears that the parents or guardians, through ignorance, fanaticism, or for arbitrary reasons, have become derelict in their duty and failed to perform it. As a necessary corollary, the further question presented is whether the parents were neglectful in this case, and, if so, whether proper discretion was exercised by the learned Judge of the Children's Court of Westchester County, if it be determined that such right exists in the State.

"The law is not only zealous in the protection of the

"The law is not only zealous in the protection of the civil rights of infants but has a special regard for the moral care, training and guidance of children,' as was written in People ex rel. Deordio v. Palmer (230 App. Div. 397); but its beneficence extends also to conservation of the health of children, their physical well-being, as well as to the preservation of their lives. If parents or guardians neglect their duty in respect to any one of those obligations, the State in its wisdom, through its laws, intervenes. While the question now before us has never been presented to an appellate court in this State in so far as I am able to determine, power in the court

to act rests upon ample authority.
"Prior to the adoption of the Children's Court Act of the State of New York in 1922, resting upon constitutional edict, there existed no affirmative statutory power to exercise direct control over the physical welfare of a child. Action was indirect, by punishment of those vested with responsibility for neglect of the health of children in failing to furnish medical attendance when needed, in violation of the Penal Law (citing cases). Such a law remains upon our statute books (Penal Law, Scction 482) and provides that one who, under a duty to furnish medical or surgical attendance to a minor, wilfully omits to perform that duty is guilty of a misde-meanor. That provision of the Penal Law is not inconsistent with the Act controlling here, which goes further, and, instead of punishing those guilty of neglecting children, which procedure conceivably might be entirely abortive, permits the State to assume the obligation and responsibility, and in the interest of the child and for its present and future welfare renders unto it the necessary medical or surgical treatment."

In holding that the Act in question was valid, the Court said:

LEGAL

'In my opinion the act is constitutional. The infant was properly before the court. The court is authorized in a proper case to make an order directing that a surgical operation be performed upon a child, and the only question remaining is whether or not the discretion of the court was properly exercised in this case. Main festly, it was the intent of the legislature to invest the court with wide powers of discretion to be exercised on the advice of competent medical or surgical authority, ininfluenced by the whims or arbitrary determination of parents or guardians in advancing the well-being of the child.'

In conclusion the opinion of the Appellate Divi-

'Medicine and surgery are not exact sciences and the result of an operation may not be forefold with accuracy Decision must be made and the parents persist in their refusal to consent. Children come into the world help less subject to all the ills to which flesh is her. They are entitled to the benefit of all laws made for their protection—whether affecting their property, their personal rights or their persons—by the legislature, the sovereign power of the State. The learned court has acted in this erie not only in strict compliance with the law but with scrupillous care and moderation and upon ample and competent proof. His discretion should not be disturbed.'

Subsequent to the said ittling, the operation was performed upon the child, and your Counsel has recently been advised that the child is progressing very well

As one of the metropolitan newspapers stated editorially

'Since this ease lies in a borderland wherein the respective rights of parents and of the State are but viguely defined, the decision becomes important as law and precedent. It is different from those simpler eases in which statutory penalties may be imposed upon parents for neglecting their cluidren. Although it is plan enough that the consequences of willful neglect will justify punishment, it is by no means clear how far the courts may go in prescribing a course of conduct in advance of putative neglect which has not yet produced these consequences.

these consequences
"The Appellate Division holds that the Constitution and statutes of New York confer full authority upon the State to require an operation for the Vasko child. If that is indeed the law it is logical to suppose that by an extension of this reasoning the State may go even fur ther. It is not however, of the law so much as of the prognant human issues involved that the public is now thinking. Those who applied the decision will not with hold a meed of sympthy for these unlargey parents upon whom cruel circumstances has laid a hand so here."

Another newspaper editorial made the following comment

It is the first case of the kind ever decided in this state. It shows the courts at their highest earnestly seeking to meet a social responsibility for this baby's life and happiness. It also shows how far we have come from earlier ideas of parental power and state responsibility. Yet at the same time it seems to remind one, in a sudden flash how difficult are the problems of men how close is that dark reality of insecurity, death and unhappiness over which the finest of civilization's efforts in law and medicine and education have thrown only a fragile bridge.

The justice and propriety of the action taken in this case can scarcely be questioned. It must lowever, not be taken as authority for the proposition that operations which are indicated can be indiscriminately ordered for children against the wishes of their parents. The jurisdiction conferred by law upon the Children's Court is purely statutory, and must be strictly construed and only resorted to in carefully considered cases.

BURN FROM ELECTRICAL KNIFE

A physician, specializing in surgery, was called upon to perform an operation upon a married woman about forty years of age, for chronic infected Bartholm's gland. Another doctor acted as anesthetist at the operation and administered to the plaintiff an anesthetic of avertin supplemented by introus oxide and oxygen. The usual inhalation mask was used consisting of a metal hood protected by a rubber inflated cushion. The surgeon performed the operation on the patient, using an electrical surgical knife which consisted of a needle on the end of an electric cord.

The operation itself was performed uneventully, and after the operation was over the gas machine mask was removed from the patient's face by the anesthetist. Both doctors noticed a blister on the end of the patient's nose about the size of a pea. Neither doctor could explain the manner in which the blister had been caused. Unguentine was applied to the blister on the patient's nose. The patient recovered from the effects of her operation successfully. The burn on her nose, however, took a few weeks to heal, and

a permanent scar about one quarter mich in diameter, somewhat pitted remained

Action was commenced against both the sur geon and the anesthetist, charging them with negligence in the performance of the operation and seeking to recover for damages alleged to have resulted from the burn on the patient's nose Before the action came on for trial the anesthetist died, and the action therefore abated as to him The case was continued, however, against the surgeon and the action was brought on and tried Testimony was intro before a judge and jury duced on behalf of the plaintiff by an electrical engineer to the effect that the burn must have been caused by the surgeon grounding his electrical knife against the operating table, whence the current was conducted, through a series of solid bodies to the nose of the plaintiff. An electrical expert testifying on behalf of the doctor gave testimony to refute the said rather strained explanation of how the injury occurred case was sent to the jury, who returned a verdict in favor of the defendant surgeon

NEWS NOTES

THE BUDGET

The following budget of expense of the don Heyd, Frederic E. Sondern, and Daniel Medical Society of the State of New York for the year beginning July 1, 1933. and ending June 30, 1934, was prepared by the

S. Dougherty. It was approved by the Executive Committee of the Council, and adopted by the Trustees on June 1, 1933 in accordance with

CONFERENCE ON ASPHYXIAL DEATH

The all-day conference on the subject of Asphy val Deaths of which notice was given in this Journal of May 15, page 662, was held on May 24, with entire success. The subjects of asphy via and resuscitation were discussed from every angle, and the uninimous conclusion of those in attendance was that every hospital and ambulance should be equipped with the facilities for doing resuscitation, and that the modern method of the intratracheal insufflation of ovegen should be taught to every hospital interne

The addresses given at the conference may be classified in four series —

I Those dealing with the physiology of respiration and the changed conditions in asphysia, with special reference to the role of carbon dioxide as a respiratory stimulant, and to the alkali reserve and so-called acidosis

2 The newer methods of treating asphysia, including the use of oxygen mixed with seven per cent of carbon dioxide. The particular pieces of the apparatus discussed and described

were respirators of the Drinker type, the inhalation mask and the direct vision laryn goseope for intratracheal insufflation

3 The conditions in which the newer methods were of special value, including carbon monoxide poisoning drowning, electric shock and asphysia of the newborn

4 The relation of non medical agencies to the newer methods, including policemen and firemen, ambulance surgeons and all others engaged in first aid work

The principles of asphysia and resuscitation are easily understood, and their practical application is standardized and may be made readily. The newly formed Society for the Prevention of Asphysial Deaths, whose headquarters are in the Building of the New York Academy of Medicine, 2 East 103rd Street, New York City, is preparing to supply lecturers and demonstrators to medical societies and hospital staffs in order to familiarize physicians generally with the newer methods of resuscitation.

DEDICATION OF MERCK RESEARCH LABORATORY

The new Research Laboratory of Merck & Co, Inc., manufacturers of pharmaceuticals, Rahway, N J, was dedicated on the afternoon of Tuesday, April 25th, 1933, in the presence of over three hundred guests composed of distinguished seicntists, laboratory workers, physicians and representatives of other manufacturing companies Mr George W Merck, President of the Company, presided, and explained the object of the new laboratory

The principal speaker was Sir Henry H Dale M D, FRS, whose subject was "The Relation of Research in Universities to Research Supported by Industry" Dr Dale set forth the essential services rendered by manufacturing com-

panies, not only in maintaining high standards in the manufacture of therapeutic products, but also in making discoveries in the field of pure science, comparable in importance with those made in universities. The paper was of such interest to physicians that it is printed on page 723 of this Journal

The list of speakers included—Dr Hugh S Cumning, Surgeon General, United States Public Health Service, Lammot du Pont, President Manufacturing Chemists' Association, and Josiah K Lilly, American Drug Manufacturers' Association

The visitors were entertained in the new building after the exercises

KINGS COUNTY

Diphtheria Immunization The June issue of the Bulletin of the Medical Society of the County of Kings contains the following appeal from Dr Shirley W Wynne, Commissioner of Health of the City of New York

"It was decided to make another concerted effort to arouse parents in Brooklyn to the necessity for diphtheria immunization because Brooklyn mothers have lagged so far behind that only about fifty per cent of the children under the age of ten years are now immunized

Brooklyn still leads every other Borough in diphtheria cases and diphtheria deaths. Up to May 20 there had been thirty nine deaths from diphtheria in the entire city for 1933, and twenty-one of these deaths were in Brooklyn

"Diphtheria immunization in Brooklyn in 1932 totalled 61,805, of which 10,931 were given by private physicians. So far this year the same ratio seems to exist, but we believe that our new attack will lead to more immunizations by the private practitioner.

"It is intended to make every boy and girl in Brooklyn a public health officer during the life of the campaign, and if possible beyond that period. Coupons are being published in the various daily and weekly papers published in Brooklyn and these coupons are presented by the juvenile health officers to mothers or fathers of children from the age of nine months to six years. The parents are asked to agree to have their children immunized by the family doctor, or any private practitioner in the neighborhood, and the name and address of the physician so selected is written on the coupon. If the parents are unable to pay the fee of the private doctor, they agree to take the children to the Department of Health Baby Health Station nearest their home.

"These coupons are sent directly to the Bureau of Health Education of the Department of Health, and the boy and girl sending in the greatest number of coupons will receive suitable prizes, as will some ninety-eight other youngsters, graded according to the total of coupons returned. Clerks in the Bureau of Health Education will sort out these coupons and mail then, to the physicians whose names have been written in at the request of the parents.

"After the close of the contest each doctor to whom coupons have been sent will be requested to notify the Bureau of Health Education as to the number of parents who have lived up to their promise and have had their children immunized, as well as those who have failed to do so. Immediately upon receipt of this information Department of Health nurses will begin checking up and will make every effort to have the children of these parents taken to the offices of the respective doctors.

"We believe that the campaign, as above outlined, while not the first house to house canvass we have made in Brooklyn, will have the dual effect of a house to house canvass and bring to the fore the importance of diphtheria immunization. Added to this will be the spirit of competition among the young solicitors who, because of family ties, friendship or ability to convince, will be able to get many signatures to coupons which otherwise would be impossible.

"The campaign will reach its peak when in Prospect Park on Saturday, June 24, at 2:30 p.m., the Brooklyn Child Health Festival will take place. It will be distinctly a Brooklyn event with Borough President Henry Hesterberg as chairman."

NASSAU COUNTY

The regular monthly meeting of the Nassau County Medical Society was held June first in the Bar Association Building in Mineola. The meeting was entirely on the subject of Medical

Economics in Nassau County.

The Committee on Economics of the Nassau County Society has been studying the report of the National Committee on the Costs of Medical Care, and gave an extensive survey of Nassau County's problem in the light of that report. Exceptional credit is due Dr. Everett Jessup for his devotion to this work.

The first part of the report of the local committee was a comparison of the factual data in Nassau County, read by Dr. P. A. Williams. He presented the figures for the rate of growth of population, and the ratio of doctors, specialists, nurses and hospital beds per capita; and outlined the present clinic system, concluding that free clinics were not needed.

Dr. David Gurin read a careful criticism of

the report of the National Committee.

Dr. E. R. Nodine presented the final conclusions of the Nassau County committee, which included the following recommendations:—

1. A Medical Examiner's office to replace the coroner's.

2. The creation of a public health plan similar to that of Detroit.

3. The continuance of state aid to unemployed through private physicians.

4. The formulation of a hospital insurance

4. ine formuli lan.

5. The election of physicians to the directing boards of the hospitals and lay organizations.

6. The adoption of a special decreased price for x-ray examination of chests where tuberculosis is suspected.

7. The establishment of more semi-private

beds in the hospitals of the county.

The guest speaker, Dr. F. E. Elliott of Brooklyn, Chairman of the Committee on Economics of the Medical Society of the State of New York, commended the Nassau County Medical Society for its complete analysis of the local situation.

Dr. Charles Goodrich of Brooklyn and Dr. William H. Ross, of Suffolk County, added their commendations to that of Dr. Elliott, and talked briefly on the present economic problems of the practicing physicians of the County of Nassau.

THE DAILY PRESS

MEDICAL PATENTS

The address of Dr. Henry II. Dale at the dedication of the Research Laboratory of Merck. & Co., Inc., which is printed on page 723 of this Journal, elicited editorial comments of some of the Metropolitan dailies on the subject of medical patents. It is not surprising that editorial writers should not understand that the object of securing patents on drings and biologicals used in medicine is not merely money profit, but that a still more powerful incentive is that of controlling the methods of manufacture so that the product shall be of imiform quality and potency. Some views of laymen regarding medical patents are disclosed in the following editorials.—

The Brooklyn Lagle of April 27, says -

Profit and regulation do not absolutely exclude each other, but they make bid companions at times Sir Henry said enough to disturb lay understanding of the purpose and handling of in

stitutionalized pitents in medicine

"Profit making from a patent on a product that may save life is not in itself any more reprehensible in medicine than it is in the devising of better fire escapes or better functing devices for ships boats. But the medical profession has long followed certain generous ideas on the subject, and as for learned medical institutions, they generally and fairly claim the honor of being run for the public benefit. Those to which the remarks of Sir Henry may apply might do well to explain fully the finances of any patents that they hold."

The New York Times of May 1, says — 'There certainly has been no worshipping of false gods in the laboratories of the great German and American industrial organizations. Such Nobel Prize winners as Lingmuir, Bosch and

Bergius won their laurels as the employes of wealthy corporations Indeed, certain kinds of research can apparently be conducted most effectricly only with the financial aid and equipment of an industrial laboratory. If we want to learn anything about low-pressure chemistry, we must go to the General Electric Company, the best information on speech and hearing is likely to be obtained from the Bell Telephone Laboratories, the Eastman Kodak Laboratories are the recognized authorities on photochemistry The larger and more liberal corporations have learned to leave their research staffs alone Even pure science cannot help making discoveries that yield a profit when exploited with the aid of patents

'Yet physicians as a class will endorse Sir Henry's warning Deep down in all of us there is a repiignance to making money out of human suffering Even the men in university laboratories who patent their medical discoveries share They apply at least part of their royalties to conducting fresh research But it is a question whether royalties do not quench the disinterestedness that is the very essence of pure research A patented drug becomes the object of jealous Is it likely that the merits of a competitive product will be objectively appraised and conceded? Questions such as these were probably uppermost in Sir Henry's mind No doubt the men who have given us patented insulin, patented liver extract and patented ergosterol can be trusted to observe the medical tradition there is a clear need for some method which will enable a researcher to obtain the money that he needs and yet pursue his studies with a serenity that knows nothing of profits'

MILK REGULATIONS

The Department of Health of the City of New York has consistently promoted the highest practical standards in the production and sale of milk For years it has advocated the abolition of the sale of loose milk, and at last the availability and low price of pure milk in saintary containers his enabled it to forbid the sale of any other form of milk Commenting on the new regulation the New York Times of June 2 says editorially—

"Social historians will note that the legal suppression of the sale of loose milk in New York City came at a time of widespread intemployment and result int hardship and want. In other words at a time when the word "starvation" is not infrequently met when the community seemingly ought to be glad to have milk of any grade for the workless and the poor we actually go in for raising food standards

"The reason is, of course, that the word "starvation" does not justly apply to our present distresses. If there are people among us who go hungry, it is due to mischance and not to the lack of means for relief or the will to help. We are not in such dire straits that we must call a halt in the steady upward murch toward better food, better housing and a better life for our people."

NOTICE OF LIABILITY INSURANCE

It is sometimes difficult to interpret the provisions of an insurance policy in Workmen's compensation. The New York Sun of May 10 has the following editorial on a case which will be of

interest to physicians:—

"Having a staff of five domestic servants in his Saratoga residence, Mr. Wait voluntarily took out a policy of workmen's compensation insurance to protect himself and his employees. He was not required by law to do this. One of the servants was a nurse 59 years old who took care of a small girl. She received \$42 a week wages, board and lodging and transportation to and from her own home in another part of the city. When Mrs. Walt was driving the nurse to her home the car struck a rut in the street and the nurse received an injury to her spine, disabling her.

"The nurse brought an action for negligence against Mrs. Wait and the jury gave her a verdict of \$47,362. On appeal Mrs. Wait contended that she and her husband were coemployers of the nurse and that the case came under the work-men's compensation law. The Waits testified that in compliance with the law they had posted notices of compensation insurance in their home. The nurse said she had never seen the notices. The Court of Appeals has confirmed the verdict of the jury on the ground that even assuming the existence of an insurance policy covering the case, a question of fact was involved as to whether the notices were properly posted. It is common practice to take a receipt from each employee to the effect that he has seen the notice posted according to law and is aware of its contents."

ASPHYXIAL DEATHS

The meeting of the Society for the Prevention of Asphyxial Death, Inc., in the New York Academy of Medicine on May 24, reported on page 771 of this Journal, received the following editorial comment in the New York Times of May 26:—

"Only at first sight is there an odd touch about a Society for the Prevention of Asphyxial Death. Where is the enemy to be attacked, like the dread bacillus of tuberculosis or the unidentified agent that lurks behind cancer? Yet a moment's reflection will show that it is the magnitude of the problem which constitutes the challenge. What

difference does it make whether the toll of human life is paid to a micro-organism or to human carelessness and indifference?

"Asphyxia takes 50,000 lives annually in this country. This is more than half the number slain by tuberculosis and more than one-third the number of cancer victims. Carbon monoxide, as the run of the daily news has made plain, is one of the chief causes. The ancient evil of overlaying kills many infants in New York City. First on the society's program is the effort to educate the community, and in particular its health agencies, in the technique of resuscitation."

DEAF INDIANS

Dr. A. Hrdlicka, Curator of the Division of Physical Anthropology of the United States National Museum, Washington, D. C., is the author of an article entitled "Seven Prehistoric Américan Skulls with Complete Absence of External Auditory Meatus," which has just been published in the American Journal of Physical Anthropology, Volume 17, Number 3. Commenting editorially on these defects of hearing among the American Indians, the New York Sun of May 25, says:—

"That is strange, heretical doctrine that Dr. Hrdlicka propounds to the effect that approximately 30 per cent of all Indians in North America before the white man came were hard of hearing. If the doctor should wander out of the anthropological wilderness where in he habitually makes his camp and into the hands of a group of school boys he is likely to be scalped forthwithif school boys of today are as well up on their Indian lore, real and imagined, as were their

fathers and grandfathers. To assert that any Indian cannot see further or hear better than any Pale Face is to strike at a central article of faith, and to say that thirty out of every hundred were defective of hearing is to court trouble in such

dogmatic company.

"Yet Dr. Hrdlicka does so say. Examination of skulls taken from graves from Peru to Alaska has disclosed innumerable internal growths which, he asserts, must inevitably have interfered with normal hearing. These were never found in children's skulls, so the inference is that they developed in late youth and middle age. In some districts as many as 32 per cent of adult skulls showed this evidence of auditory defect."

A note from Dr. Hrdlicka to this Journal says: "An exhaustive treatise on the subject 'Ear Exostoses' is being printed in book form by Charles C. Thomas, 220 East Monroe Street, Springfield, Illinois, and is to appear in the latter part of this year."

BOOKS RECEIVED

- Acknowledgment of all hooks received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits or in the interests of our readers.
- DISEASES OF TRADESMEN BY BERNARDING RAMAZZINI 1633-1714 Compiled by Herman Goodman, M.D., bound with "Silk Hundlers' Disease of the Skin," by Herman Goodman M.D. 12010 of 95 pages, illustrated New York, Medical Lay Press, [c. 1933] Cloth, \$150
- Dietetics for the Clinician By Milton A Bridges MD Octavo of 666 pages Philadelphin, Lea & Febiger, 1933 Cloth \$6.50

BOOK REVIEWS

HANDBUCH DER ALLGEMEINEN HÄMATOLOGIE. Band I, Hälfte I and II. HERAUSGEGEBEN VON PROF. DR. HANS HIRSCHFELD, and PRIMARIUS DR. ANTON HITTMAIR. Large Octavo of 1523 pages, illustrated. Berlin, Urban & Schwarzenberg, 1932. Paper, RM 139.

This work is to be published in two volumes, and is a compilation of various fundamental haematologic subjects by acknowledged masters in the field.

The first part of volume one includes a consideration of the normal and pathological morphology of the erythrocyte; the chemistry of the erythrocytes and Haemoglobin; the normal and pathological morphology of the leucocytes of the circulating blood; the chemistry of the leucocytes; the normal and pathological physiology of the leucocytes, the blood and vegetative nervous system, the blood platelets and hemokonia; blood formation in the embryo; the metabolism of the blood and blood volume.

The second part of volume one concerns itself with leucocytosis and leucopenia; the lymphatic apparatus and its relation to blood cell formation in the light of physiologic and pathologic research; the lymph, normal and pathological physiology of the spleen; the bone marrow and reticulo-endothelial system; comparative morphology of blood; the blood and the cells of inflammation; the cytology of exudates and transudates.

This work, which will probably remain the masterpicce in its field for a long time reflects the minds and herculean labors of its contributors.

MAURICE MORRISON.

Organized Medical Service at Fort Benning, Georgia. By I. S. Falk, Ph.D. Octavo of 119 pages. Chicago, The University of Chicago Press, [c. 1932]. Paper, 90c. (Publications of the Committee on the Costs of Medical Care: No. 21.)

THE FUNDAMENTALS OF GOOD MEDICAL CARE. By ROGER I. LEE, M.D. and LEWIS W. JONES, Ph.D. Octavo of 302 pages. Chicago, The University of Chicago Press, [c. 1933]. Cloth, \$2.50. (Publications of the Committee on the Costs of Medical Care: No. 22.)

SURVEYS OF THE MEDICAL FACILITIES IN THREE REPRESENTATIVE SOUTHERN COUNTIES. By C. St. C. GUILD, M.D. Octavo of 173 pages. Chicago, The University of Chicago Press, [c. 1932]. Paper, \$1.00. (Publications of the Committee on the Costs of Medical Care: No. 23.)

THE INCOMES OF PHYSICIANS. By MAURICE LEVEN, Ph.D. Octavo of 135 pages. Chicago, The University of Chicago Press, [c. 1932]. Cloth, \$2.00. (Publications of the Committee on the Costs of Medical Care: No. 24.)

THE ABILITY TO PAY FOR MEDICAL CARE. By LOUIS S. REED, Ph.D. Octavo of 107 pages. Chicago, The University of Chicago Press [c. 1933]. Cloth, \$2.00. (Publications of the Committee on the Costs of Medical Care: No. 25.)

THE INCIDENCE OF ILLNESS AND THE RECEIPT AND COSTS OF MEDICAL CARE AMONG REPRESENTATIVE FAMILIES. Ry I. S. FALK, Ph.D., MARGARET C. KLEN and NATHAN SINAI, D.P.H. Octavo of 327 pages. Chicago, The University of Chicago Press [c. 1933]. Cloth, \$3.00. (Publications of the Committee on the Costs of Medical Care: No. 26.)

THE COSTS OF MEDICAL CARE. A Summary of Investigations on the Economic Aspects of the Prevention and Care of Illness. By I. S. Falk, Ph.D., C. Rufus Rorem, Ph.D., and Martha D. Ring. Octavo of 623 pages. Chicago, The University of Chicago Press, [c. 1933]. Cloth, \$4.00. (Publications of the Committee on the Costs of Medical Care: No. 27.)

Publications 21 to 26 inclusive like the twenty which have preceded them, describe in detail particular studies made by the research workers and investigators of the Committee. Space does not permit a review of each of these volumes, but their titles indicate the subject matter under consideration.

Publication 27, a book of over 600 pages summarizes the economic aspects of the prevention and care of illness. The material is compiled from data appearing in the preceding publications, plus information derived from inquiries pursued by other agencies. The topics are grouped to conform with the final recommendations of the Committee. Special consideration is given to the subjects of Group Service and Group Payments.

The amount of material in these 27 volumes is enor-

The amount of material in these 27 volumes is enormous. The questions and problems arising therefrom are varied and complex. The solution of these problems is by no means as simple as the final recommendations of the Committee in volume 28 would have us believe.

It seems a pity that the Committee did not conclude its researches and investigations with a series of questions raised and suggestions made, rather than with specific conclusions reached. By so doing, there would have been a rational basis for discussion of the many problems.

A. E. Shipley

Endocrine Medicine. By William Engelbach, M.D. Volumes 1, 2, 3 and an Index Volume. Octavo of 1795 pages, and 933 illustrations. Springfield, Illinois, Charles C. Thomas, 1932. Cloth, \$35.00.

It is given but to few people to see their own memorial erected within their lifetime. The late Dr. Engelbach has lived to see the publication of his monumental monograph on Endocrine Medicine, which was greeted by the medical profession with the approval due to such a remarkable accomplishment. The wealth of material accumulated in the course of years and the tremendous amount of labor required for the minute study of the cases described is truly impressive. Previous contributions to endocrinology by other authors were either restricted to the study of one particular gland or to even minor details while a few more comprehensive publications of the past labored under the lack of scientific exactitude. Dr. Engelbach's work is the first comprehensive survey of clinical endocrinology, based on both competent clinical studies and exact laboratory procedures. The tremendous strides recently made in the study of endocrine physiology were fortunately utilized in Dr. Engelbach's investigations. Thus the result is truly representative of the present status of our knowledge concerning function and pathology of the endocrine glands and their clinical manifestations.

Dr. Engelbach's greatest single contribution is the systematic classification of endocrinopathies according to the age period of their onset. Deficiencies or hyperfunctions of endocrine glands yield different results if they develop in early childhood, adolescence or adult life. Accordingly the clinical picture is altogether different and can not be properly understood unless the cardinal influence of the age factor is taken into consideration. Most impressive also are Dr. Engelbach's x-ray studies concerning the skeletal development. Influence of endo-

777

crine glands upon development and growth of the bones was known for some time, but the painstaking studies of Dr. Engelbach were needed to systematize our knowledge in this field. The charts which so profusely illuminate all three volumes make it possible now even for the average practitioner to recognize the different skeletal changes, in their relationship to the various endocrine disorders and enable him to draw the proper diagnostic conclusions. A fourth volume containing an extensive bibliography and general index greatly enhances the uscfulness of this work.

One may disagree with the author's views in some of the minor details. It is equally sure that our attitude concerning some other points will change with the rapid development of endocrinology, but this does not diminish in any way the great value of Dr. Engelbach's work which will remain the standard book for many years M. A. GOLIZIEHER. to come.

SURGICAL CLINICS OF NORTH AMERICA. Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, \$16.00 net; paper, \$12.00 net.

Vol. 12, No. 1. February, 1932. (Chicago Number.)

This issue contains thirty-three articles covering general surgery and many of its special fields such as oral and nose and throat surgery, G-U. and neuro-surgery. The selections have been made with good judgment and their presentation is excellent. The illustrations are as usual more than adequate.

Vol. 12, No. 2. April, 1932. (New York Number.)

This issue emanates from the prominent clinics of Manhattan. Material is always plentiful in these clinics and it has been used successfully to make this number sting one. Particularly valu-ns from the clinic of C. G.

of the liver and gall-bladder, the thyroid.

Vol. 12, No. 3. June, 1932. (Lahey Clinic Number.)

The papers from this famous clinic are ever a source of inspiration to the surgeon. Clarity, terseness and practical importance characterize each one of the thirtyfive articles. The illustrations are not very numerous but all of them are adequate and well executed. The articles on Gall-bladder surgery are timely and reflect the mature judgment of the authors

Vol. 12, No. 4. August, 1932. (Mayo Clinic Number.)

This issue contains a wealth of clinical material gathered from the various surgical specialties of the Mayo Clinie. The articles are, as usual, terse, yet complete in every important detail. The illustrations are numerous and exceptionally good.

Vol. 12, No. 5. October, 1932. (Chicago Number.)

The first forty pages of this volume are devoted to a discussion of gallstone disease from the clinic of Doctor Bevan. It is complete and includes the interpretation of cholecystographic examinations. Other articles of note in this issue are the ones on bone tumors by Ryerson, on electro coagulation in oto-laryngology, on cancer of the recto-sigmoid, on chordotomy in intractable pain and numerous case-reports with comment and discussion.

Vol. 12, No. 6. December, 1932. (Philadelphia Number.)

This issue bristles with timely and practical articles. Babcock describes, in a distressingly short article, his one-stage operation for cancer of the rectum. Gastrointestinal hemorrhage is very completely discussed by

Eliason. Every surgical specialty is given space and just attention. The volume is closed by a very instructive discussion on surgical drainage by Crossan,

GEORGE WEBB.

THE PRACTICAL MEDICINE SERIES. Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Series 1932. General Medicine. Edited by George H. Weaver, M.D., and others. 12mo of 837 pages, illustrated. Chicago, The Year Book Publish-ers, [e. 1932]. Cloth, \$5.00.

As usual, this book furnishes a very useful review of the year's work in the field of General Medicine, abstracts from the leading journals are not too brief and are taken from 107 publications in different countries. The sequence as formerly used is followed. In the group of infectious diseases, stramonium finds increased use in Encephalitis, a specific antiscrum is reported for use in Tularemia and Undulant Fever is stated to have shown remarkable improvement from whole blood transfusions.

In the section on chest diseases the article of C. A. Hedblom after twelve years of study of Empyema is notable, also a summary of Pneumonia. The section on Diseases of the Blood, in addition to recent articles on Pernicious Anemia has several on the hypochromic or microcytic anemias. Disease of the Heart and Blood Vessels. Gastro-intestinal Tract, of the Kidneys and of Metabolism also receive adequate attention.

W. E. McCollom.

THE PRACTICAL MEDICINE SFRIES Comprising Eight Volumes on the Year's Progress in Medicine and Survolumes on the rear's Progress in Medicine and Surgery. Scries 1932. Chicago, The Year Book Publishers, [c. 1933]. General Surgery. Edited by Evarts A. Graham, M.D. 12mo of 816 pages, illustrated. Cloth, \$3.00

This is a volume from a scries which is welcomed each year by workers in various fields. The 1932 volume on Surgery is essentially the same in its make-up as previous volumes, containing more than 740 pages of abstracts on practically all of the surgical topics. There is an interesting group of abstracts on anesthesia. Several new operative procedures and improvements in technique have been described. Most notable of these is a scaleniothey for immobilization of the apex of the lung in tuberculosis. There are some very good abstracts of articles relating to gastrectomy and its benefits and effects upon the production of anemia and digestive disturbances. As always, this volume is a valuable asset to the practitioner of surgery for reference to the magazine literature appearing since previous volumes.

HERBERT T. WIKLE

A GUIDE TO HUMAN PARASITOLOGY FOR MEDICAL PRAC-TITIONERS. By D. B. BLACKLOCK, M.D., and T. Southiwell, D.Sc., Ph.D. Octavo of 271 pages, illustrated. Baltimore, Williams & Wilkins Company, 1932. Cloth, \$4.00.

The various phases of parasitology are only briefly discussed, although in a rather concise and impressive manner. The simplicity with which the discussion and classification of the subject is undertaken, renders the book a very valuable text to the technician, student and graduate. Certain phases of the subject lack, however, complete detailed description to render the book of particular value to the post-graduate worker in parasitology, who is seeking instructions for Diplomas of Tropical Medicine, Tropical Hygiene and Public Health. The diagrammatic presentation of the life history of the more eommon parasites, affixed to the end of the book, is a very ingenious way of impressing the more important facts on the mind of the reader. J. RABINOVITCH.

CONTRACT PRACTICE IN WASHINGTON

The April issue of *Northwest Medicine* has the following newsy editorial on contract practice in the State of Washington:

"The chaotic state of medical practice at the present time is a disturbing reality to the whole medical profession. During recent years groups of physicians and individual practitioners have rivaled each other in developing mass practice in order to attach to themselves as large a number of people as possible, ignoring the equal privilege for practice of the individual physician: form of practice has extended to such an extent that the existence of the old time general practitioner seems to be in danger of annihilation. To make the matter worse, comes the report of the Committee on the Costs of Medical Care which substantially endorses this threatening form of practice, advising the employment of the same principles in grouping patients in clinics connected with medical schools and hospitals. Naturally the many medical practitioners not included in these favored groups have become greatly disturbed as to their own future existence and have felt the necessity of considering methods by which they may compete with this apparently overwhelming trend toward concentration of practice in the hands of a few.

"The conditions of medical practice as they exist today may be illustrated by the situation in Seattle, Washington, which can be duplicated in other large cities. Data pertaining to contracts under the State Department of Labor and Industries are most available and illustrate the greedy spirit by which certain individuals have attempted to corral the practice of the state. The most hoggish example of this selfish practice is presented by Bridge of Tacoma, whose clinic has been industriously worked in Seattle so that out of one hundred and thirteen of the contracts this clinic controls fifty-five. A rival Tacoma group, the State Clinic, has annexed twenty-two contracts, while twenty other physicians or groups of the city have thirty-seven, twelve of these being possessed by one man. This demonstrates how the work under the state supervision is concentrated in the hands of a few practitioners. This, however, is not the cream of contract practice in Seattle. Including those mentioned in the above citation certain groups and individuals have systematically solicited the nonhazardous industries which are not under state control, such as department stores, hotels, restaurants, police, fire department, in short, any concern which employs a The profit herein lies not

so much in treating these individuals under contract, as the invitation at cut rates also to care for the members of their families and their friends. Naturally, likewise, they expect to treat at more favorable rates conditions not included in the contract, such as obstetrics, venereal, alcoholic and tuberculous diseases. This enumeration certainly presents a formidable concentration of medical practice, from which the bulk of practitioners are excluded.

"How to meet this situation has been the subject of much discussion. Expulsion from the medical society was the remedy in the early days, when contract practice was represented by the lodge doctor. Commonly he retained his practice while retiring from the society, later to be welcomed into the fold when his objectionable form of practice was terminated. This form of discipline today would wreck the medical society; since so many are engaged in it. The conclusion appears to be accepted that the only successful procedure will be to fight the devil with his own In other words, the county medical weapons. society in some form will supervise contract practice on the part of all members who wish to participate in it, adopting some methods hitherto condemned as unethical, but which seem necessary for successful competition with the other contractors.

"In Washington, under the designation of County Society Bureau, Yakima County Society has satisfactorily conducted such form of contract practice during the past year, including its entire membership. Pierce County Society launched such an enterprise during the past year, supported by some eighty per cent of its membership. In Oregon this form of practice has been carried on for the past two years by Marion County Medical Society and Salem physicians report it a success. In Multnomah County there has been a similar enterprise functioning during the past year, including a large proportion of the society membership. In California at least two county societies have conducted contract practice for some time and report satisfactory progress.

"In Seattle, King County society has appointed committees which have devoted much time to the study of contract practice by its members, and last month at one of the largest meetings in the history of the organization, it adopted without expressed opposition the launching of this form of practice. They have endeavored to profit by the experiences of other societies, hoping to over-

PABLUM requires no cooking

Pre-cooked Mead's Cereal, dried-ready to serve

Consists of wheatmeal, catmeal, cornmeal, wheat embryo, yeast, alfalfa leaf and beef bone. Supplies vitamins A, B, E and G and calcium, phosphorus, iron, copper and other essential minerals.

PRACTICAL ADVANTAGES TO THE MOTHER. The preparation of ordinary cercal for the infant's diet is one of the most irksome of the mother's many duties. To her, it usually means getting up an hour earlier in the morning. It means bendung over a hot stove in sunner. It means guessing at the nmount of cercal to cook, with unavoidable waste and scraping and boiling of pots, pans and cookspoons.

With Pablum, all the mother need do is to measure directly into the baby's cereal bowl the prescribed amount and then gradually add the prescribed amount of previously boiled water, milk or milk-andwater (hot, warm or cold) until desired consistency is obtained. Re-

cooking is not essential, but may be done if desired.

For older children and adults, this case of preparation makes Pablum especially welcome in families where the benefits of hot cereals are often denied simply because the process of cooking ordinary cereals is too long and too bothersome. Pablum can be prepared in a minute for one or several members of n family.

Pablum, being dry, although pre-cooked, keeps indefinitely and requires no refrigeration. Moreover, since it is dry only cereal is paid for, not added water. Hence Pablum is "economical,—no waste."

MEASURE PRESCRIBED AMOUNT INTO CEREAL BOWL

ADD HOT WATER AND

ADD MILK OR CREAM (Sugar to taste for older children ond adults)

PABLUM

SUPILIED IN 1 FOUND CARTONS AT DRUG STORES

Like Mead's Cereal, Pablum represents a great advance among cereals in that it is richer in minerals

drates and calories—and unlike many foods that are "good for growing children," Pablum tastes good.

(Continued from page 778)

come some of the pitfalls which have been en countered, and to adopt the most satisfactor method of procedure that can be determined. An member of the county society may become member of the contract organization which wil be incorporated independently of the county so ciety but supervised by it. There will be a limita tion to the amount of practice that any member can attain during a single month, in order to pre vent a limited number accumulating the bulk of the work. An executive committee will have ab solute authority in the management of the enterprise. Since patients will have the choice from a large number of physicians, it is hoped that the personal contact between physician and the patient may be preserved in a manner not possible with the restrictions of a small group. If this form of practice develops to the satisfaction of all con cerned, it is expected it may counteract the objections of certain forms of contract practice which seem so destrutive in their nature.'

LEGISLATION IN INDIANA

The April issue of the Journal of the Indiana State Medical Association contains the following report on medical legislation in the State:

'Although a number of side issues and innumerable skirmishes took place, so far as the medical profession was concerned, the session may be divided into three major battles: the first, the cult battle; the second, against those who wanted to tax the physician and limit the fee he should charge for prescribing medicinal whiskey;

and the third, the tax battle.

"Many of the members of the general assembly had gained the conception that the medical profession was a closed corporation and a 'trust' which was keeping competing practitioners from other schools of healing out of Indiana merely for selfish reasons. Several of the members of the public health committee in the House were convinced this was a fact until the entire truth of the situation was explained to them, most effectively in the majority of cases by their own family physician. Nevertheless when the public hearing was called, things looked a bit uncertain. But if things looked uncertain before the hearing, when the spokesman for the chiropractors had completed a most impressive presentation of his side of the case, it was doubly uncertain as to how a group of laymen, such as largely made up the public health committee in the Whatever their senti-House, would react. ments and predilections may have been when they came to Indianapolis, and no matter how good a speaker the chiropractors had to advocate their cause, the committee reported the bill out with a unanimous recommendation for

ABSORPTION CONTROL

-Guarantees Surgically Safe Sutures-

Dependable absorption is the most important requirement of a suture. Yet the suture that lasts too long, the suture that absorbs too quickly, and the suture that has a definite and controlled absorption rate all look alike!

How can you judge the safe suture? By evaluating the methods used by the manufacturer to insure correct absorption.

Three factors are of utmost importance in the control of a suture's absorption rate: first, the character of the raw catgut; second, the accuracy of gauging; third, the adequacy of the chromicizing process.

Strands of raw catgut appear to be exactly alike to the eye—yet they often differ greatly in quality. Careful selection methods insure uniform characteristics in Curity raw materials.

Next the gut is gauged with the utmost possible precision. Delicate iostrumeots reveal the slightest variations. Only strands which are uniform within safe limits are approved.

The Curity chromicizing process is based oo years of research and improvement. The result is complete and even chromicization.

These control methods are your assurance that the specified digestion rate of Curity sutures is accurately and defiaitely measured. Samples for clinical trial will be sent on request.

Red - Ripe WHOLE Tomatoes—Pressed Into FULL-BODIED Juice

The nutritional qualities of Kemp's SUN-RAYED Tomato Juice are those of choice, red-ripe, WHOLE tomatoes. Nothing removed except skins, seeds and cores. Nothing added except slight amount of table salt for seasoning.

The special Kemp process liquefies all the valuable tomato solids, resulting in an appetizing, full-bodied juice of high nutritional value. VITAMIN POTENCY PROVED by scientific feeding tests. Obtainable at leading chain and independent food stores in the New York district

Write for copy of Steenbock report, showing nutritional importance of full-bodied, whole tomato juice over thin juices containing only a portion of the tomato solids.

THE SUN-RAYED COMPANY

FRANKFORT, INDIANA

(Division of Kemp Bros. Packing Co.)

(Continued from page 780—adv. x) indefinite postponement because of the following reasons:

- (1) The committee did not desire to create another state board.
- (2) The committee did not feel that a chiropractor should be empowered by law to do more than manipulate the spine.
- (3) The committee did not feel that the chiropractors should be allowed to do minor surgery (as they would have been allowed under the bill).
- (4) The committee did not want to give the chiropractors preferential rights over a regularly licensed physician before the compensation board.
- (5) The committee was not at all certain that chiropractors should be allowed to enter hospitals and state institutions on the same basis as a physician.

"The committee report was adopted by a voice vote in the House. But the trouble was far from over. Scarcely had the original chiropractic bill been killed than a bill that would strike out the injunction clause in the medical practice act and would leave the act without teeth was introduced. This was reported out of committee for indefinite postponement and was killed by a voice vote on the floor of the House."

The Senate also killed a Chiropractic bill which had been introduced during the last week of the legislative session.

A bill to tax physicians one dollar for each prescription for alcoholic liquor was proposed. The Journal says:

"It wasn't the fact that they were limited to a \$1.00 prescription fee that particularly concerned the committee, as much as the fact that the General Assembly of Indiana should place any limit on any fee that a physician might'charge for any prescription. That would be the entering wedge of state regulation of fees—a start in state medicine! So after various conferences with the authors of the bill and those in high places, your committee finally gained their consent to take off the prescription limitation fee.

"As the bill passed the House and went over to the Senate, it seemed harmless enough as far as the medical profession was concerned, but somehow, someway, when the bill passed the Senate a fifty-cent tax per pint was attached to be paid by the physician! This came about as the distillers, wholesalers and retailers were all battling as to who should pay the state tax and they finally decided on a compromise suitable to all of them—the tax should be paid by the doctor who wrote the prescription. This

(Continued on page 783-adv. xiii)

(Continued from page 782-adv. An)

sent your committee scurrying about once again, when this disturbing fact was discovered, for there remained only one chance to straighten this out—that was in the conference committee, if the House could be induced not to concur in the Senate amendments and a conference committee could be appointed which would agree to the change. This was quite some job but it was done and the tax was taken off the doctor."

The Legislature passed a law imposing a tax of one per cent on all gross incomes, including those of physicians. Commenting on this tax, Mr. Albert Stump, Attorney of the State Association says.

"The physician and surgeon would be required to pay a gross income tax of one per cent on all fees charged, including the funds collected by him for the cost of medicines used if he dispenses the incdicine himself. expression above quoted, 'without any deductions on account of losses,' in my opinion refers to losses that might be sustained through any causes whatever connected with this profession or business. But it does not mean losses of potential income through the failure to collect accounts The income is to be levied upon the actual receipts total amount of the actual receipts, and not the total amount of what may be on the books, is the basis of the computation of the gross income tax One might sustain losses on account of the deterioration of supplies and equipment, or through automobile accidents, or fire, or other such incidents, and that class of losses could not be deducted. The failure to collect an account, however, is not strictly a loss as the term is used in this Act, for in that event there never had been a realization of any compensation which could be lost. The account, until it is collected, would stand as a mere possibility of an item of income which would be realized and taxable only as of the time when it was collected."

VITAL STATISTICS IN TEXAS

The May number of the Texas State Journal of Medicine is promoting the efficient registration of births and deaths by printing the following editorial:—

"It will be remembered that a short while ago the Census Bureau made a test of the registration of births and deaths in Texas, in an effort to secure the admission of Texas into the Registration Area As it stands, Texas is, as it was then, the only state in the United States not admitted to this area. The Census

(Continued from page 783-adv. xiii)

ureau is embarrassed, and Texas should be shamed. The decision to prosecute a test at his time is but an extension of the favors the ureau of the Census has been extending exas through several years in this connection. Not alone should it be worth our entervor to secure admission to the Registrator of Area as a matter of pride, but as a matter of appreciation also.

"It will be recalled that the requirement is nat 90 per cent of the births and deaths actually occurring in the state be shown to have een officially filed. The Bureau of the Census handling to a definite and very large proportion of our people post-card questionnaires, eaking data as to births and deaths. When the energy destionnaires are returned actual comparison will be made, and thus the percentage of reports of births and deaths will be determined. If 90 per cent of them have been exported, we are in the Registration Area and ill be accorded the distinction of being up-to-ate, at least in the bookkeeping of public ealth, and numerous advantages otherwise,

ome of them worth money.
"How can we as a profession help? By
imply seeing to it that the births occurring

in our individual and collective practices have been promptly registered. Undertakers are presumed to take care of deaths, but occasionally deaths occur outside of the range and knowledge of undertakers, exactly as sometimes births occur outside of the knowledge and range of physicians. We can help under such circumstances as this if we will, perhaps not greatly from an individual standpoint but collectively quite considerably. If the State Health Department can be informed of the circumstances surrounding these border-line birth and death cases, steps may be taken to secure reports from responsible parties, whomsoever they may be.

"We feel that it is hardly necessary to dilate upon the advantages—nay necessity, of proper vital statistics. Health work may not be satisfactorily carried on except in connection with reports of birth, sickness and death. Particularly is the matter of birth reports important to the individual. There are so many opportunities for embarrassment in this connection, and even distress, that we hesitate to undertake to discuss them. Doubtless our readers are advised, and if so our plea for a one hundred per cent registration of births, anyway, will be more effective."

A Maternity Support Typed for the Large Woman

N properly fitting an expectant mother with a maternity support, a tall, slender figure requires a straight-line model; a small, petite figure, a short, lightly boned one; a large, well-developed figure, a full, long-hipped one. Camp garments are proportioned to all figure types in stature and other individual respects.

An example of a proper model for the large woman with heavy thighs (No. 3123) is illustrated on an actual seven-month pregnancy case. Like all Camp maternity supports it possesses the exclusive Camp Patented Adjustment feature which adapts it to figure and to changes in pregnancy. In this case, it has one set of adjustment straps with extra lacing from waist to top. It provides firm under-abdominal and sacro-iliac support and relieves undue pressure on organs.

Approved and recommended by leading physicians. Sold by Sungical, Drug and Department Stones and Corset Shops. Write for Physician's Manual.

VENEREAL CLINICS IN MASSACHUSETTS

The New England Journal of Medicine of February 16, discusses venereal clinics in the following editorial:

"It is impossible, at least in the present stage civilization, to quarantine those persons afflicted with syphilis or gonorrhea; the only inportant way in which the State can exercise any control over them is by making certain that throughout the Commonwealth proper facilities

are provided for their treatment.

"The Department of Health is correct in assuming that this matter cannot be left entirely in the hands of the individual practitioner. Many physicians are unwilling to treat patients with syphilis or gonorrhea; a study recently conducted by the Department of Health shows that only 46 per cent of Massachusetts physicians admit that they treat gonnerhea and only 39 per cent admit that they treat syphilis. A proportion of those who do accept these cases are undeniably not qualified to eare for them properly. Aside from these considerations, there are many patients who are unable to pay the cost of adequate treatment by private physicians.

The best way to meet these conditions, the State has wisely decided, is by the establishment of clinics. Clinics can be geographically located to respond to the distribution of patients; in clinics, those physicians in each community who are best trained to care for gonorrhea and syphilis can be further trained and utilized to best advantage; clinics can be assisted financially and educationally in a way that individual physicians cannot be, and can be kept under supervision to make certain that they maintain a minimum

standard of efficiency.

"Twenty-eight public elinics have been so established, but it must be understood that none of these are maintained or operated by the State Department of Health. All but six are located in and maintained as a part of the out-patient departments of general hospitals or general dispensaries. Fourteen of these clinics have received financial aid from the State, the annual subsidy varying from \$500 to \$1,200, and totaling \$12,000. The amount contributed by the State has been but a small proportion of the cost of maintaining these clinics; it has amounted to approximately one dollar per year per registered case, or a little over six cents per visit. In addition to the subsidies, the State distributes free of cost arsenicals for the treatment of syphilis. The drugs so distributed to the clinics cost the State about \$5,000 a year. The fourteen elinies aided by the State admit in the neighborhood of 2,200 new eases of syphilis and 2,700 or 2,800 new eases of gonorrhea each year.

"The State Department of Health has recently prepared a set of Minimum Standards for Clinics

for the Treatment of Gonorrhea and Syphilis. (Continued on page 786-adv. avi)

THE RATIONAL METHOD OF CHANGING THE FLORA

Theories come and theories go, but the most rational method of changing the flora so far developed is the Lacto-Dextrin way -- providing a proper "soil" in the bowel, to encourage the growth of the b. acidophilus and b. bifidus.

Many authorities have confirmed that intestinal putrefaction can be combated by supplying the right carbohydrate foods - lactose and dextrin,

Lacto-Dextrin makes these foods available in a palatable, practical way.

BATTLE CREEK LACTO-DEXTRIN

(Lactose 73% — Dextrin 25%)

changes the flora - promotes normal bowel activity - reduces the possibility of toxic absorption - is a food, not a drug - is easy to take - can be prescribed for any patient.

SARATOGA GEYSER

A Naturally Carbonated Mineral Water

STATE OWNED AND STATE BOTTLED

S ARATOGA Geyser, because of its natural carbonation and high content of calcium bicarbonate and sodium bicarbonate, has proven of great value where alkali is indicated. It is particularly beneficial as an aid in the alleviation of the acidosis of gout, rheumatism, neuritis and diabetes mellitus; as an aid to digestion in the various gastric neuroses and in the relief of hyperacidity. Because of the sodium chlorid in Saratoga Geyser, it is not recommended for patients with nephritis.

The waters at Saratoga are the only naturally carbonated waters found in the United States east of the Rocky Mountains and have been characterized

by well known members of the profession as the peer of any to be found in Europe. The State of New York, recognizing the great value of these waters, has taken over their control in order to prevent their waste and to facilitate their proper use.

Upon written request, we will gladly send a complete analysis and a complimentary carton of Saratoga mineral waters for clinical tests, including 2 bottles of Geyser and 1 bottle each of Hathorn and Coesa.

GEYSER WATER

(Continued from page 785-adv 1v)

These standards prescribe the physical equipment and the personnel of a clinic, formulate general rules pertaining to frequency of visits, and state the requirements which must be met before the patient may be discharged as cured. These 'Minimum Standards' have been submitted for criticism to various venereologists and to the Neisserian Society of Massachusetts and to the New England Dermatological Society, both of which have officially expressed their approval

"It is not at all infrequent to discover that a physician not interested in the management of gonorrhea or syphilis will refer a patient, perfectly able to pay a physician, to the nearest clinic rather than to some physician who does treat these diseases. The Lowell Clinic turns back to some twenty or thirty physicians each year almost as many cases as are referred to the clinic by physicians.

"It is difficult to see how the State Department of Health could better meet the challenge of syphilis and gonorrhea than through the establishment of these clinics. Opportunity for adequate care is provided for the indigent; and for those who can afford to pay, physicians are being trained to help them through their difficult hours. A standard of treatment is set up in every community; if the public will but take advantages of these opportunities, the danger of communicating these diseases to others will be materially reduced."

DOCTORS AND THE HEALTH BOARD OF TENNESSEE

The Journal of the Tennessee State Medical Association of April contains the following editorial description of an attempt to reorganize the Health Department of the State:—

"Members of the Association received copies of the bill to re-organize the health department. You were told that the bill had the approval of all the committees of the State Association that were concerned: the approval of the Governor and the approval of the Commissioner of Health. These statements were facts The bill was introduced, passed first and second reading and came up for hearing before the Committee on Public Health and Sanitation on March 23.

"The profession sought to have placed over the State Department of Health a board of governors, or councilors, whose duty it would be to make sound policies and not to destroy activities as has been alleged so often.

"To the great astonishment of the Legislative Committee a large number of people were brought to the hearing by members of local health units and over the state by members of the State De-

(Continued on page 787-adv. xvii)

Please mention the JOURNAL when writing to advertisers

(Continued from page 786-adv. xvi)

partment in opposition to the bill. The Commissioner did not appear to lend his endorsement to it.

"The members of the local health units and the people they brought with them applauded the slurs hurled at the medical profession. The principal slur was that the medical profession was prompted by motives of selfishness in sponsoring this bill.

"It is becoming increasingly obvious that the Public Health organization in Tennessee is better organized for political activities than it is for health protection. To support this statement two facts are cited:—

"First, appropriations for the department were increased enormously in the bicnnium now ending, notwithstanding the fact that our state was in the midst of the worst depression ever known; that our school teachers were not paid; that taxes are delinquent on a high percentage of homes and at a time when almost everybody was agreed that expenditures by the state should be reduced.

"The next fact of importance is that a comparison of the mortality rates from preventable causes in counties with full time health units with the rates in counties without full time health units shows a difference in mortality so slight as to be negligible.

"In fact there are counties in the state without full time health units with a mortality rate more favorable than counties with a full time health unit. Robertson county without a health unit and Montgomery with a health unit are examples.

"It has been intimated time and again that the medical profession was prompted entirely by selfishness, in the face of the fact that the medical profession of Tennessee has taken care of the indigent sick without cost during this entire depression. It has carried the burden uncomplaintingly, but the point is approaching, in fact it has already been suggested that the medical profession will not much longer carry the burden of earing for the indigent sick while various public agencies draw handsome salaries for giving medical care to the well-to-do.

"The question then is not whether the state has local health units or not, it is not whether the State Health Department has larger or smaller sums to spend or whether this or that person is the head of the department. The real question is, 'Shall the state continue on a course which leads to communism and do it in the false name of health?'

"Should that day come, the public will have brought about through false leadership and false philosophy, the most tragic circumstances that can be imagined. It will then be a communistic system of medical practice.

"We do not believe that the people of Tennessee, if informed, would travel a road that leads to such an end."

THE MENACE OF VITAMIN D DEFICIENCY

during pregnancy

No private an needs to be told how critical the prematal period is to both mother and child. Even a slight Vitamin D deficiency at this time may manifest itself in softening of the mother's bones and teeth—or may scriously affect the developing foctus.

For Vitamin D, as you know, controls the absorption and utilization of calcium and phosphorus; and the demand for these two essential minerals is at least twice as great during pregnancy as under normal conditions.

Mnny physicians safeguard the developing child—and protect the mother's boncs and teeth—by prescribing Cocomalt. It contains not less than 30 Steenbock (300 ADMA) units of Vitamin D per ounce. Prepared as directed, cach glass is equivalent in Vitamin D content to not less than two-thirds of a teaspoonful of standard cod liver oil. Laboratory analyses show that Cocomalt increases the protein content of milk 45%—the carbohydrate content 184%—the mineral content (calcium and phosphorus) 48%.

Comes in powder form—at grocers and drug stores in ½-lb, and 1-lb, cans. Also in 5-lb, cans for hospital use, at a special price.

Cocomalt is accepted by the Campitles on

30,540,000

MATERNAL MORTALITY IN PHILADELPHIA

The April issue of the *Pennsylvania Medical Journal* discusses maternal mortality in Philadelphia as follows:

"According to the records of the Department of Public Health, Philadelphia, there were reported in 1932, sixty-three cases of puerperal septicemia with sixty-two deaths. Evidently only those patients the physician thought would die, were reported.

"Notwithstanding all that has been said and done regarding the lowering of maternal mortality, very little is being accomplished. The distressing feature is the inability to secure the cooperation of the one who most of all needs proper instruction—the general practitioner.

"The Committee on Maternal Welfare, of the Philadelphia County Medical Society, under the able chairmanship of Dr. Philip F. Williams, has worked most valiantly during the past two years upon the reduction of maternal mortality from

every possible angle.

"As a grand climax the Committee arranged for an identical program to be used in eight different sections of the city at 9.15 p.m. February sixteenth. It was thought that the time arranged would allow the physicians to complete their evening office hours and arrive on time for the meeting that was being held in their respective communities. The outline of the program was arranged by Dr. Barton Cooke Hirst, in order that the subject matter would be uniformly covered in all centers. The program was divided into three papers. The readers of the papers did not live in the center to which they were assigned. The chairman of the meeting, however, was a local physician.

"It is of extreme interest to note that with all the details worked out, the publicity of the meetings given in the county society's publication, and a last minute reminder by a postal card notice to all members of the county society, there was a total attendance of 120 at all the eight meetings. Of this number, eight were the chairmen; twenty-four were the readers of the papers, and the remainder, ninety-three, were the audience (eleven plus at a meeting) and the greater number of these were specially interested in obstetrics.

"The most frequent cause of maternal death is infection and it is the most certainly avoidable. Two-thirds of the maternal deaths in childbirth are due to three causes: Infection, hemorrhage, and toxemia.

COMMITTEE ON PUBLICATION

MEDICAL POOR RELIEF IN INDIANA

The May number of the Journal of the Indiana State Medical Association describes the plan of medical relief of the poor adopted in Grant County. This is a rural county in the north central part of the State having an area of about 400 square miles, and about 35,000 population. The Journal says:

"With the advent of Reconstruction Finance Corporation funds in the county came also a Governor's Committee on Relief for the entire county. They took the profit out of the furnishing of food, fuel, and clothing to the indigent, and felt that the profit must also come out of the furnishing of medical relief. They asked that the Grant County Medical Society submit a plan to do this, with the understanding that this was an emergency and that the question of funds in the county was critical.

"The essence of the agreement as stated in the first paragraph is good faith. It is based on a desire of the Governor's Committee and the county commissioners to furnish the best medical service possible at the least eost. The members agree to furnish the same type service to the indigent as they do to their private patients, but with the understanding that they shall render the minimum of service in keeping with good medical or surgical judgment; and that the service shall be rendered to only those cases in actual need of the services. Services that may be postponed or withheld without threat to life or important function shall not be rendered under the agreement.

"The county is divided into eight districts, each of which includes a town and the surrounding territory. In the Marion district and in such other districts as may seem necessary there is to be set up a sick call headquarters where all calls for medical aid are to come. These headquarters are to be in charge of investigators who shall investigate the case, call the doctor if necessary, and follow the case through its entirety. Where the applicant for services has no choice of doctor, the doctors are to be called in rotation. There is a special fee scheduled for this agreement which is from 50 to 75 per cent below the minimum of our former schedule. Any disputes are provided for by setting up of an adjudication committee of two doctors and one layman who will review the case, and their decision is final. Bills are checked; and if any question arises about the bill, it is referred to the committee for settlement. Time alone will tell if this method of handling the problem will be satisfactory. Our only hope is that it will keep the practice of medicine in the hands of the physician, where it rightfully belongs."

Two pages of the article set forth the agreements and the fees.

by prescribing tablets.

Each tablet of Phillips' Milk of Magnesia contains in concentrated form a teaspoonful of liquid milk of magnesia, thus simplifying the dosage.

The pleasant taste, convenience of taking and absence of unpleasant after-effects all combine to appeal to your patient's comfort.

For those who travel, especially, you will find that Phillips' Milk of Magnesia Tablets supply a long-felt want.

anced meal without the slightest digestive strain. Its high caloric value and easy digestibility make it especially effective in helping to throw off that nervous, devitalized feeling of which so many patients complain — unless, of

course, there is some serious, chronic ailment which must be corrected.

Cocomalt is an honest food, ethically advertised. It is accepted by the Committee on Foods of The American Medical Association. Laboratory analysis show that Cocomalt increases the protein content of milk 45%—the carbohydrate content 184%—the mineral content (calcium and phosphorus) 45%. It contains not less than 30 Steenbock (300 ADMA) units of Vitamin D per ounce—the amount used to make one glass or cup.

Cocomalt mixed with milk is especially useful in pregnancy and lactation, in illness and convalescence, and for underweight, malnourished children.—Adv.

AN INTERESTING LETTER

I was cleaning out an old well yesterday that hadn't been used out of or any one lived around for over five years, and what do you think I found? One of your small cans of Zinc Stearate Merck Powder in the bottom.

I picked it up, saw the pictures of all the ducks and read all the printing on the can. When I read—it sheds water like a duck—that caused me to investigate and what do you think I found when I removed the top? A can about half full of powder and the remainder of the can filled with water. I poured the water off and let the powder remain in the can. The powder was just as dry and dusty as any powder could be.

I think your powder is a little better than you advertised it; you said it would shed water like a duck. Well I believe a duck would leak a little if it would stay in water for five years without coming out. I am almost sure the can of powder had been in the well for at least five years, if not longer.—Adv.

July 1, 1933

THE FIRST DECADE OF THE SECOND CENTURY OF THE MEDICAL SOCIETY OF THE COUNTY OF KINGS

By FRANK D JENNINGS, M.D., BROOKLYN, N. Y.

Read before the Medical Society of the County of Kings March 21 1933

T the end of 1922 certain unsatisfactors situations existed in the Medical Society of the County of Kings There was disaffection in some quarters based on a feeling that the Society had been inactive when adverse legislation threatened Our inaguificent home, in proportion to its potentialities, was used relatively little. Individuals, to be sure, visited the Regular monthly meetings scientific in character, were held Special societies met in the section room The atmosphere generally was that of a closter Membership languished We had gone through tremendously active legislative years contending against measures which we deemed unwise among them compulsory health insurance, health centers, narcotic bills, sundry and varied, workmen's compensation law chiropractic and osteopathic measures, the Sheppard Towner Act, the proposed statute compelling each physician to have a female attendant in his office and annual registration measures, proposed annually from 1919 on We learned that as a potent, medico civic unit we fell somewhat short of the mark, even in the public health field. We had no Bulletin Contacts with legislators were casual The Professional Guild was an alert and efficient agency in those forays on Capitol Hill up which so many of us marched, up and down

That may serve as a reminder of the atmosphere then Have we stood still or have we progressed? To answer these questions has imposed in the writer the pleasant duty of scanning the records of our organization for the decade. To have read them thus collectively, is to have read an opic of progress that is breath taking. To peruse in cold type, from year to vear, the annuls of this Society, recording as they do effort loyalty and devotion without end, is soul satisfying. The pithways of 1923 very definitely pointed to certain needs and duties, viz.

- I Larger membership
- 2 Greater utilization of our property for all purposes, and the creation here, if you like, of a medical center

- 3 A clearly defined need for wider and more purposeful educational opportunities in the graduate field not wholly uset by monthly scientific assemblage.
- 4 Greater coupliasis on our public health activities
- 5 The carrying on of our great library, a public service and duty, on the most liberal basis
- 6 The strengthening of our structure and the broadening of our influence as the representative medical organization of the County of Kings

With that as a basis let us view retrospectively this span of ten years

Membership-The backbone of any organization is its membership. Ten years ago our membership was about 1,250 and at the end of 1932 was approximately 2 100 a gain of 850 members The increase is substantial and has been effected only because of valiant effort on the part of the Membership Committees from year to year Our membership in proportion to the total number of physicians in the county remains about the same, roughly sixty per cent The difficult times of the last four years have operated to keep our membership down and there is every reason to believe that with the return of better times our membership will continue to show an in crease and reach a total that will be ninety per cent, or more of the available physicians in the counts

The Headquarters—The Library Building has come to be a real medical center. The regular meetings of the Society, the Friday afternoon lectures of which 223 have been given, the meetings of the Special and Dental Societies, the steady and increased influx of visitors to our hibrary, the great number of eallers, both Iay and medical the location here of a Health Department station have all combined to make our home an exceptionally busy place. The incoming telephone calls from members and others seeking information of all kinds are amazingly numerous For example, during eleven months of 1929,

when an effort was made by the Society to establish a Bureau of Information and Guidance, the total number of inquiries, both in person and by telephone, were nearly 1,800, of which 573 emanated from physicians, 535 from lay individuals, and 124 from organizations. The character of these requests for information was most astonishingly varied, and gives an excellent idea of what a dynamic and beneficent force such a Bureau could be, had the Society been able to continue it. As it is now our over-worked and numerically small staff carries on, doing a most wonderful job in helping to make this the real health information center of the county. It is no news to say that we have long since outgrown our present quarters. However, during the decade there has been greater and greater use of this building in all ways, the increasing demands on it only emphasizing the inevitability of expansion.

Graduate Education—In 1923 there was increasing appreciation of the necessity for wider and better planned educational opportunities for all the doctors in the county. The Friday afternoon lectures had evoked great popular response, illustrating anew the avidity of the medical profession for knowledge. Beginning modestly, and with no little apprehension, the lectures were continued and immediate consideration given as to the best and most practical way of enlarging the service that this Society might render in the field of graduate medical education.

A committee on graduate medical education was formed and a liaison established with the then Long Island College Hospital leading to joint and mutual effort on the part of both organizations functioning through a joint committee. The work of this committee was that of a pioneer in every sense. Under its planning and leadership during the decade 417 graduate courses were offered in 19 branches of medicines, and for these courses 1,922 doctors registered. Eighteen of our local hospitals participated, throwing open their facilities to the matriculants. Over a hundred of the medical profession of Brooklyn

engaged in teaching.

No more significant, or more practical, or more valuable step has ever been taken in the field of graduate teaching than this, so aptly termed "The Brooklyn Idea." Any physician practicing medicine in this county who sought to improve himself, to widen his knowledge, to make himself a better doctor, had ample opportunity to gratify these ambitions without leaving home or practice. The effect and influence of this plan in improving the standard of practice in this community cannot even remotely be estimated. The obligation rests on every county medical society to do all that it can to bring about and maintain the highest standard of practice possible. In that connection, no county society within our knowledge has made any greater effort than ours, the successful consummation of which was made possible by the fortunate and happy combination with out local medical school, now the Long Island College of Medicine.

The Library—The carrying on of our great library as a public service and duty on the most liberal basis possible is a manifest obligation. You will recall that Dr. Bradley Parker in his inaugural address as president in 1844 broached the idea of a library. As a result a committee was formed which one year later, 1845, reported a library of 60 volumes and a balance of \$50.00. Such was the modest beginning of that possession which marks us as distinguished and unique among county medical societies. In the fabrication and perpetuation of our library many names shine with lustre notably Dr. Joseph Hunt who started the first, formal library organization. He secured a salaried, part-time librarian and in addition classified and indexed material himself. He installed the collection in our first home at Bridge Street and threw the doors open making it a true public library. Equally notable has been the inspired and devotedly unremitting service of the Nestor of our organization and our profession, William Browning. This brief mention is pitifully scant homage to one of the finest medical citizens Brooklyn has ever known. It is not too much to say, Mr. President, that a special meeting might well be set aside in honor of Browning so that he might know to the full in his life time something of our admiration and affection for him. Some measure of the growth and demands on the library may be gleaned from the following figures. In 1922, 5670 individuals made use of the library taking out and consulting 13,087 volumes; and in 1932, 12,538 individuals used and withdrew from the library 59,491 volumes, increases respectively of over one hundred per cent in borrowers and over four hundred per cent in books borrowed. This does not take into account the use of journals, and it is of interest to record that we now receive 1509 journals from all over the world and in all languages. We receive more current Russian journals than any other library with the possible exception of the Surgeon-General's and New York Academy of Medicine Libraries. The number of volumes at present is estimated as 130,000 and our library ranks fourth after the Surgeon-General's.

Through these years, under the wise counsel of Drs. Browning and Rushmore, Mr. Frankenberger has continued to conduct the library on a high plane. He is most indefatigable. His recent trip to Europe, made possible by our Medical Library Association of Brooklyn, resulted in the enrichment of our library with many medical publications and old medical classics. In addition, he lectures at Long Island College of Medicine in Medical Literature and Medical Bibliology.

ology.

Corporate Structive-A radical revision to which our constitution and by-laws were subjected by a committee headed by Dr Charles A Gordon did much to strengthen our corporate struc-It provided for many changes and simplified and clarified the old constitution materially It created a number of new committees, discarded some old ones, provided for greater latitude in membership viz, student, intern, associate and wisely enlarged the Board of Trustees from five to fifteen, a number more in consonance with the increased membership and increasing responsibili-There have been changes ties of the Trustees made in this instrument since that time all of which have represented advances, notable among them the provision for the office of President Elect allowing the holder of that office one year in which to prepare for the duties of the presi-The importance and significance of these changes are self evident

Our influence has steadily widened because of the initiation of new activities and broadening of

old ones

Milk Commission—The milk commission has held the level of efficiency which has marked its work since its inception in 1901 with Dr E H Bartley as chairman. The production of certified milk has continued the assurance to our great constituency of clean, raw milk. The certification of our milk commission still stands on a pinnacle of its own. The details of the work of the commission constitute a most faseinating story which is commended to you for reading. A readjustment of the relationship of the Milk Commission to the parent society, brought about by the vision, wisdom and forcefulness of Dr. John E. Jennings, contributed immeasurably to more harmonious and efficient functioning of the commission

Illegal Practice—The Committee on Illegal Practice was instituted in 1923 Its first chairman was Dr Joseph E Golding who established a close entente with the District Attorney's office, the Health Department and the County Clerk Much valuable work was done in chiminating from our borough charlatans and illegal practitioners His successors have carried on this work with great fidelity among whom was the late Dr Joseph Behan, whose sudden death was a great loss Since 1926 when the Webb Loomis bill became a statute this committee has worked with the Gricvance Committee of the State Department of Education This combination seems to be operating efficiently as a report from that Department in February, 1932, showed that during 1931 and for the first two months in 1932 42 cases for complaint had arisen in Kings County, in 21 of which there was no cause for In 9, violations were stopped without prosecution There were 12 criminal prosecutions with 11 convictions and one awaiting trial at the time of the report The work done by the Committee on Illegal Practice is a community service of the first rank, one of the many tendered by this great organization

Press Reference Committee-This Committee came into existence during 1924 during the administration of Dr Charles A Gordon As, in many of our activities, this was a pioneering adventure. It was created to provide an instrumentality to which the Press might turn for information on medical matters and through which organized medicine niight speak. It so happens that the speaker has been chairman of this committee during its existence. While it is true that the plan has not accomplished all that we hoped for and that mistakes have occurred, it is equally true that during these nine years there has been a minimum of the publication of stories glorifying quacks and charlatans. No more cures for the blind or for caneer have been exploited in the columns of our local press. It would be impossible to compute the number of stories that have been denied publication because of the existence m our borough of such an agency as this, to which the gentlemen of the "Fourth Estate" could turn when in doubt. The Society through this committee has rendered a very distinct community service which has undeniably enhanced our civie standing

The Bulletin—A factor steadily growing in importance and in further improving our standing and influence is the monthly "Bulletin". Drs Gordon and Welton were its Acconclicurs and Editors during its infancy, until 1926 when Dr Alec N. Thomson was appointed Editor. Under use detorial guidance and supervision the "Bulletin" both in format and content is a splendid publication, a dignified, efficient and houest representative of a great Society, a welcome visitor everywhere. Its circulation is about 4,000

During the years under consideration many other publications appeared under the aegis of the Society and its committees, many of which have escaped your memory. Some were in conjunction with the Brooklyn Chamber of Commerce Brooklyn Tuberculosis and Health Association, the Health Department of the City of New York and others. As a reminder for us all of these phases of our work Dr. Thomson and Mr. Frankenberger have grouped them in the form of an exhibit, which hangs on the north wall of the anditorium.

Coordinating Committee of Fire County Societies—In 1926, when Dr Humpstone was our Chief Executive, he invited to a meeting all the presidents of the county medical societies in the greater eity taking office in January of that year for the purpose of discussing problems of city wide import and of interest to the medical profession. Following the first meeting, many more followed in the months and years that ensued. It became increasingly evident that only by joint effort of this character could organized medicine be heard as a unit in the greater city. A plan of organization has been evolved after long consideration providing that the committee will consist of three members from each county society, its President and two members, each of the latter to serve two years.

The Committee is restricted to consideration of matters involving community welfare from the medical point of view, and the relation of the profession thereto. It reports to the component county societies with its recommendations and acts officially only upon authorization by them.

The central office, or headquarters, is at this address. The Chairman now is Dr. Walter Lud-

lum, the Secretary Dr. Alec N. Thomson.

To illustrate the varied questions and problems that pass in review by this Committee let me cite the following:

1. Neighborhood Health Centers and Districts.

- 2. Cooperation with the Welfare Council in relation to Health Administration and Education.
- 3. Health examination work in continuation schools.
- 4. Municipal Hospital Law in reference to the remuneration of physicians for caring for those injured and coming under the provisions of the Workmen's Compensation Act.

5. Physiotherapy in the school system.

- 6. Regulation of Clinical Laboratories under section 105 of the Sanitary Code.
 - 7. Principles of popular medical publicity.
- 8. Drug store practices and other phases of venereal disease quackery.

9. Health examination program.

10. The unemployment situation as it relates to the physician and the utilization of the physician in caring for unemployed in their homes.

There are, and have been, many others, all of vital importance to the profession and to the people we serve. It is fortunate that, in meeting and attacking these problems, unity of action by the five county societies through this committee may be attained. It is a definite milestone, very clearly in line with the suggestion made by our President in his sterling inaugural address. It is good to know that the original impulse arose here, that our members have done such sound work in the committee, that headquarters is here and that for the first time organized medicine of the great city has a legitimate mouthpiece.

Leaders—In a survey such as this it may be invidious, even dangerous, to single out individuals for mention. However, any history would be incomplete if it failed to remind you of the fine service rendered to this society by Fowler and his Centenary Celebration Committee; of the Medical Library Association and Jewett, Beck, and Charles A.

Gordon, and their unceasing work in behalf of the library; of John J. O'Reilly's unselfish and devoted interest in our welfare; of the late Wm. Schroeder and his thirty-one years' work on the Historical Committee; of Babbott's generous and numerous gifts to the library; and of our unknown benefactor whose grant has exceeded eleven thousand dollars.

Medical Economics—There are left, then, for review two of our committees, two of transcendent importance to us as individual physicians, to the Society and to the public. Of these, let us first consider that of Medical Economics. For the first half of the decade the annual reports do not register a great deal of activity, the latter half is a different story as economic picture changed. McGoldrick and his committee have had to face and cope with very serious and fundamental problems, among them, the abuses of well baby stations, the ever present dispensary problem, medical representation on hospital board of managers, the rates to physicians for electric current in their offices and homes, the administration of the Workmen's Compensation Act, in which a plan of arbitration was worked out with insurance companies which is said to be giving satisfaction and aiding doctors in collecting controverted medical bills; certification of the indigent poor, central registration of such persons, and other related and kindred questions. Some are still under consideration, some have been referred to the co-ordinating committee of the five county societies.

Dr. McGoldrick has brought to the work of this committee patience, together with great insight and sagacity. They have not solved all our economic impasses. Many of them are not possible of local solution. Their answer may be written at Albany, possibly at Washington. Governmental structures are in flux the world over. What lies ahead of us no one can predict. The situation of medicine in the future governmental fabric will not be easily determined. But so long as we have gentlemen of the type of McGoldrick on our Economic Committee and Goodrich on the Economic Committee of the State Society, we may feel confident that the point of view of organized medicine will be adequately presented and that so far as lies within their power any changes to be made will be equitable, not our way, not any one's way but in the way best calculated to provide our people with honest, adequate medical service at a living honorarium for the practitioner.

Public Health and Public Relations—And now last, our Public Health and Public Relations Committee, the Committee, in the speaker's opinion, that is the most important

of all. Through it as an organized medical body we contact with more societies, organizations, and public health problems than through any other committee, in fact, more than all the others combined. Its activities are varied, often overlap those of other com-There is hardly a function of this society that does not, sooner or later, contact with this committee. Its renaissance began with Dr S R Blatters at the helm and has been carried on by Dr A E Shipley since 1924 It is difficult in such a review as this to do justice to the prodigious work done by the gentlemen of this committee, to the unending hours given by them in meeting the many difficult situations that have arisen, to their generally excellent judgment and particularly to the practical and well thoughtout plans evolved by them

The organization of this committee at the beginning of the decade provided for representatives of the Health Department, of unofficial health agency workers, of industrial medicine, of women physicians, general practitioners, and those interested in neurology, surgery, venereal diseases. As time went by representatives of the local medical societies were included together with men in special branches of medicine such as gastro enterology and rochtgehology, physiotherapy, obstetries, tuberculosis and oto laryngology Personnel of this kind makes it possible for the committee to have expert coursel and ad-

vice at all times

The committee has in substantial degree through sub committees functioned on special subjects, such as blood donors, 1-ray laboratory regulations, physio-therapy radio broadcast a neer, maternity icer, maternity service lectures, of w hich nged for given through the Y M C A, Boy Scouts and other organizations, cardiac clinics, hospitals, mental hygiene As a result of their deliberations in conjunction with official agencies regulations governing blood donors and laboratories were promulgated, the standing orders of the Visiting Nurse Association were written and approved and the committee was designated as the equivalent of a Medical Advisory Board to that Association

Significant accomplishments of particular and intimate interest to us as practitioners, follow

1 Physical examination of students in continuation schools

2 The Herith Examination Idea, a Five County Procedure a direct development of the demonstration by this committee in 1924

3 The diphtheria program of the city of

New York was the outgrowth of conferences following an invitation of our President in 1925 to the Presidents of the other county societies. The first diphtheria announcement was prepared here.

4 Physical examination of children entering school for the first time was stimulated by this committee in conjunction with the Brooklyn Tuberculosis Committee and the

Department of Health and Lducation

5 The Committee has been most active and helpful in emphasizing that the fundamental purpose of Neighborhood Health Development is the promotion of health through preventive medicine, therapensis being reserved for the niedical profession

6 By its alertitess and activity no new dispensaries, other than dental, have been opened except as part of a new hospital development

7 By its vigorous action the examination of food liandlers was preserved as a function of general practice rather than is an exclusive health department function

Dr Shipley, now Professor of Preventive Medicine at Long Island College of Medicine, may well be proud of the record of the Public Health Committee as he enters the tenth year of his meumbency as Chairman Harassed by lack of funds and secretarial help, his achievement is all the more remarkable as we scan the scope and detail of the work glimpse its magnitude and infinite value to our commitmity and our society

Broad Accomplishments—Further developments of the last decade that insure the permanence of the work of the Society may be mentioned

1 The acquisition of land to provide for needed growth when funds are available

2 The creation of a general endowment fund, begun by Charles H Goodrich, and the receipt of the two largest bequests in our listors

3 The establishment of the position of Di-

rector of Medical Activities

4 The absorption of the Long Island Medical Journal into the Medical Times with a circulation of 13 000 assuring a constant flow of five hundred journals to our library

Icademy of Medicine—Ours is a record of which we may be proud and for which no apology is necessary. It is the story of an organization that has displayed a deep sense of civic obligation and social consciousness, and has endeavored to live up to both. For this period aye and longer, our functions and activities have been those of an Academy of Medicine. In recognition of this fact our corporate title has been amerided and the change was approved by the Secretary of State on Tebruary 27, 1933, to read now "The Medical So-

ciety of the County of Kings and Academy of Medicine of Brooklyn." This is a definite and significant change denoting as it does that in this jurisdiction the County Medical Society will function as such and, in addition, as an Academy of Medicine. In so doing, we will continue those activities, essentially of an academy, that have been carried on in the past and will now be in a position to bring about the development of sections in the various branches of medicine, increasing and

amplifying scientific and educational opportunities. With added emphasis on our public health work, and the increasing demands on our public medical library we shall be in better position to seek public support. As this elaborate structure stands tonight it is wholly and entirely the product of physicians, "the house that doctors built." On our record we have a right to expect that the citizenry of Brooklyn will aid and help us in maintaining and enlarging this temple of medicine.

THE INFLUENCE OF TRAUMA IN ACUTE AND CHRONIC ENCEPHALITIS* By ABRAHAM M. RABINER, M.D., NEW YORK, N. Y.

ELDOM does one meet with a patient who has not at some period had an injury of one sort or another; and so, we find trauma listed amongst the etiological factors in the great majority of clinical syndromes. Students are taught that if a given disease has a large number of causes, it is logical to regard none of them as the true cause. It is quite obvious, therefore, that we should evaluate with careful scrutiny the part that any trauma may play in disease.

That trauma plays a very important role in medicine must be accepted without hesitancy. The scope of this paper is too limited to discuss here the numerous illnesses produced, aggravated or activated by it. In later communications the relationship to certain other neurological dis-

orders will be continued.

The writer's interest on the influence of trauma in epidemic encephalitis received its impetus in 1923. Working in the laboratory of the late Professor Alfons Jakob at Hamburg, and because of his interest in certain dyskinesia syndromes, he was asked to study the brains of two cases that had presented interesting disorders of motility.

In life, the diagnosis in both instances had been dementia præcox. To the amazement of Professor Jakob and the writer, microscopic study revealed a typical picture of epidemic encephalitis. The story of antedating trauma in both patients created an added interest. A detailed study of these most unusual cases was published at the time¹. These two cases have served as a nucleus, and to them there has been added a series of cases of varying types of trauma associated with clinical pictures of epidemic encephalitis.

As is to be expected, differences of opinion exist as to the role the trauma plays. Such varying thoughts are often voiced in public and create criticism. A review of the literature reveals a veritable chaos of contradictory viewpoints.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

A paralysis agitans syndrome is a most common sequel of encephalitis. Paralysis agitans, before its dependence on basal ganglia pathology became recognized, was commonly believed to occur following trauma. In such instances the injured part of the body was regarded as the site of the disease's onset. Oppenheim² and Patrick and Mendel³ emphasized this view. Levy4, studying one hundred and forty-six cases, found a history of trauma in twenty, and also stressed the correlation between the region of the trauma and the site of the first symptoms of the disease. They did not consider the trauma predisposing in any sense except as to the site of the initial symptom.

Emotion as an occasional cause of Parkinsonism has often been described. J. A. Barré, discussing a report of J. Lhermitte and Mile. Parturier before the Paris Neurological Society, stated that during the bombardment of Strassbourg in 1870, there had been a small epidemic of paralysis agitans, and that during the World War there had been cases of sudden onset in people hidden in caves when in fear of bombardment. He also cited the case of a bricklayer who had fallen thirty feet into water, escaping physical injury, but who at once became Parkinsonian. He added further that he had seen dilated blood vessels in the basal ganglia and assumed that perhaps vasomotor disorders may bring about the syndrome in connection with emotional shock.

A. Souques expressed himself as very skeptical about the alleged emotional cases. He had investigated the Strassbourg epidemic of 1870, and found that it only included three cases. He further stated that he had never seen a convincing traumatic or emotional case, but in view of reported cases, he had to admit the possibility of a traumatic origin in rare instances.

Heussge⁶ also stresses the occurrence of rigidity and tremor first appearing in the part injured, and directs attention to the existence of proliferation of connective tissue and of sarcolemma nuclei in the affected muscles. He suggests that possibly alteration from trauma in muscle tissue may react on the central nervous system. He also cills attention to the unfavorable blood supply of the basil ganglia which may favor the occurrence there of semile changes at a relatively early age. As an illustration of this he cites the case of a 39 year old man who sustained a severe confusion of the left shoulder, and developed, two veris later, a tremor of the left land as the first symptom of paralysis agitans.

Other instances of injuries to peripheral parts of the body and subsequent development of Parkinsonian Syndrome are reported by Lotinar⁷, Sonques⁸, Klippel and Lhermitte⁸, and Grossoni¹⁰ Robert Bing¹¹ does not accept Lotinar⁸, second case I lecause the injury was to the back, and not of the head and because there had been a tremor

prior to the accident

O Cronzon, R Levy and Justin Besancon?" describe the case of a 47-year-old man who developed a typical Parkinsonian syndrome after a head injury, the tremor appearing in the right arm one month after the injury. He also presented mental dullness and a right hemianesthesia which was considered hysterical. The authors thought that training might have been a factor, but commented on the extreme scarcity of Parkinsonism in connection with the enormous number of head injury cases which had been seen during the war

Among other reported instances of Parkinsonism following trauma to the head are those of M Faure Beauhen and G Desbuquois¹¹, Mayer, Trabund¹⁴, and Guillan and Alajouanine¹⁵

With numerous reports of such neurological symptoms apparently following traumata, the opinions expressed as to their relationship may be followed with interest. Songnes evidently considers trauma of little, if any, value in these Mendel' looking with favor on a tran matic influence mentions however the necessitive for a predisposition to the disease, a determined age and a given interval between the injury and the onset of symptoms Soughes admits, however that a severe head injury may produce a strio pullidal lesion capable of giving a Parkinsonian syndrome Lambranzi allows trauma a concountant value Guillan and Alajonanine15 give to training a hypothetical value in the absence of any other pathogenic element Catola18, Marotta1, Negro 0, and Ciampolino21, are decidedly against allowing tranna any importance in this In cases of so called peripheral connection trainin, Heissge, Frahmd14, Cronzon12 and others talk of an unshackling action capable of exaggerating or bringing into evidence a symptomatology until then mobserved. Many of the observers seem opposed to the view that trauma may cause Parkinsonism. Some say that in the cases cited, the tranma is merely a coincidence, while others, basing their opinion on statistics, i. c., the rarity of cases in comparison to the numbers injured, deny it any value; and among those favorable to a traumatic influence, Cronzon¹², Faire Beaulieri and Deshiquois¹³ admit it only in crainal injuries. Kehrer¹⁷ rejects trauma completely as a cause of paralysis agitans

Out of all this complexity, Bing11 attempts to set up three definite postulates to warrant the

admission of a transmitte etiology

1 That the trainin has affected the skill, and at least must have produced the picture of concussion

2 That the injured person must be known to have been free from eerebral symptoms before

me mjiny

3 That after the injury he must have shown prodromal pons symptoms which gradually developed into those characteristic of paralysis agitans

In this paper it is not proposed to discuss so called trainmatic encephalitis. A severe head injury with at least the clinical picture of concussion may cause such cerebral pathology. It is with the clinical pictures recognized as lethargie or epidenic encephalitis and its se quicke that we are concerned. When may training be regarded as influencing such symptomatology? An analysis of such cases makes necessary grouping the problems as questions which one should attempt to answer.

1 When a patient developing acute epidemie encephalitis gives a history of a previous in jury, what effect, if any, has that injury had in the production of the disease?

2 With a listory of a previous acute encephalitis, what influence does traum; have on a later developing chronic dyskinetic syndrome such as Parkinsonism?

3 When a patient presenting a partial elinical picture of chronic encephalitis such as a fremor in one hand, etc., sustains an injury, may a later, more complete development of the chronicity be attributed to such a training?

4 What type or degree of injury should be regarded as influeneing any part of the clinical course of acute epidemic encephalitis?

Case I Acute epidemic encephalitis myoclome radicular life a mental picture resembling demental precore extensite dyskinetic phenomena and a history of cerebral concussion nine days before the onset of illness F, a 19 year old baker, on February 24th 1923 fell

F, a 19 year old baker, on February 24th 1923 fell about five feel from a lidder, landing on the sacrum For a brief period he lay unconscious. He liten climbed the ladder and continued to work but had pun over the back of the neck. After continued pain for nine drys he attempted to resume work, could not because of increased pain and went home. There then ensued stiffness of the neck pain in the right arm and twitching in the same extremity. He was then admitted to Civiliaven Hospital and from there because of motor resilessness and a speedily developing mental picture, was transferred to Friedrichsberg (Hamburg). Here he present

ed muscular rigidity with lack of associated movements, facial grimacing, rhythmic twitching of the right arm, head, and neck, and the head was held bent backward. The neurological examination revealed the dyskinesia as noted, gait was unsteady, he reeled to both sides but did not fall, speech was indistinct, and there was twitching of the lower jaw. The neurological status was otherwise negative. Psychically, he presented a peculiar picture. At times he was quite sensible and oriented, obeying orders Generally, however, he appeared confused, emotional, with visual and auditory hallucinations, and showed mannerisms. Death occurred twenty-two days after the accident.

Microscopic study revealed chief characteristic changes in the hypothalamus, pons, substantia nigra and in the floor of the fourth ventricle. There was perivascular infiltration predominantly with lymphocytes, but also with plasma cells. The infiltrating cells were always confined to the perivascular spaces, but were occasionally also found in the neighborhood of blood vessels in the parenchyma (Fig. 1). Throughout the sections, especially in the grey matter, the nuclei and ganglion cells

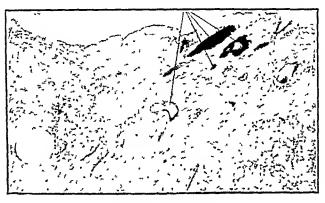

Figure 1. Case 1

Medulla oblongata. Perwascular infiltration. Markedly dilated blood vessels with fresh extravasations of blood.

Nissl stain.

showed degenerative changes and there was extensive glial proliferation. Frequently one noted extensive glial masses in which the ganglion cells had largely disappeared. In parts, the nuclear regions were so altered by formation of small vacuoles, as to give an appearance of a sieve, and one may almost speak of a finely meshed status spongiosus (Fig. 2). The perivascular spaces were considerably widened, and the vessels themselves markedly dilated; in fact many of the larger empty spaces are probably to be considered as widened perivascular spaces. In these regions the ganglion cells had undergone severe degeneration and acute swelling. It is noteworthy that these parenchymal changes were in no way dependent on the infiltration process, and that in many areas no infiltration was noted. The substantia nigra showed similar changes. Markedly dilated vessels and fresh extravasation of blood were seen in the floor of the fourth ventricle (Fig. 1). The ganglion cells of the thalamic nuclei were definitely altered, their protoplasm was clouded, the nuclei were often swollen. and pushed into eccentric positions. The pallidum was lightly involved. Many of the ganglion cells were still in good condition. On the other hand, the striatum was considerably altered in its entire extent. There was a name parently and degeneration with the rescale was a lightly and rescaled a state of the control of pure parenchymal degeneration, with no vascular infiltration. The ganglon cells, especially the small ones, took the Nissl stain poorly and their nuclei were swollen. The large ganglion cells were similarly, though to a lesser extent, affected. There was slight glial prolifera-tion, and the widely distended vessels and lymphatic spaces were striking. The infundibular region and the

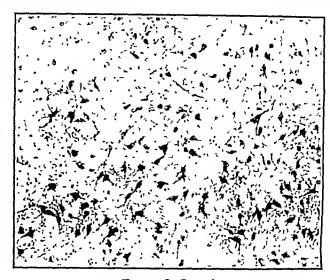

Figure 2. Case 1

Pons. Ganglion cell degeneration. Vacuole formation.

Nissl stain.

tuber cinereum showed slight parenchymal degeneration. The cortex in general showed very marked changes. In places the ganglion cells had almost entirely disappeared, and seemed as shadows of themselves. The nuclei at times appeared swollen. Foci with no cells interrupted the normal cortical architecture and were noted particularly in the frontal and temporal regions. Here the ganglion cells had disappeared and were replaced with a thin protoplasmic glial reaction. In the vicinity of these foci the remaining ganglion cells were distorted in position. These foci were predominantly in the lower layers of the cortex, laminæ IV to VII. (Fig. 3).

Comment: The pathological study of this case leaves no doubt that this man had an acute epidemic encephalitis. The changes in the basal ganglia, especially the striatum, account for the dyskinetic phenomena. The cortical findings may be considered the basis for the mental symptoms.

FIGURE 3. CASE 1
Frontal cortex. Degenerated foci in laminae VI and VII. Nissl stain.

,

The dilutation of the blood vessels and lymph spaces noted throughout the sections is of in terest in explaining the relationship the training played in the production of this extensive patho logical disorder. It is possible to assume that this man developed the encephalitis independently of the traum? Many patients have had encephalitis without ever having any transmaview however, of the litstory that the trauma was severe enough to produce a concussion, it must be regarded as capable of causing dilatation of blood or lymph spaces. If so, the door for admission of the infectious agent into the central nervous system was opened. This type of case then warrants the conclusion that a trauma suffi cient in severity to produce at least a concussion. may cause pathology that permits the entrance into the central nervous system of the infectious agent causing acute epidemic encephalitis

Case II Acute epidenne encephalitis choreo athetoid no ements a mental picture and a history of a se ere cranial minry secen years prior to ouset of illness

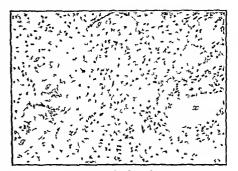

H was born in 1892. He was a laborer and had been well until 1916 when in the war he was lut on the head with a piece of an exploded shell sustained a severe con cussion and the left eye was enucleated. Though he was later able to work there was persistent headnehe and he was never considered the same as before the mjury On January 3rd 1923 he became restless excited at times was confused could not sleep developed twitch ing of the eyelids and made constant chewing move On admission to the hospital it was noted that the left eye was missing. The neurological examination was negative except for a slight right friend weakness Serology was entirely negative. He presented involun-tary movements of the entire body. He was quite sensi-ble followed all commands and was oriented in all spheres. He complained bitterly of the twitching which he could not control especially the head which at times bent backwards. He often heard voices and would winder off to a corner of the room. He showed good usight realized his condition but continued to answer the voices he thought were talking to him. The involuntary movements disappeared during sleep days the restlessness assumed a distinctly choreic char noter varying with a slower periodicity giving the im-pression of athetosis. During the last few days there developed coma with fever and death January 26th 1923

The brain appeared hyperemic. In the cortex of the third left temporal convolution in the vicinity of the corni ammonis there was embedded a clierry stone sized

ell fragment

Microscopic examination rescaled the characteristic changes of epidemic encephrilitis in the brain stem with marked lymphocytic and plasma cell infiliration price clipinal degeneration and protoplasmic glar proliferation. These changes were of served in the poins substantia mgra hypothalamus and the infundibilium. The thala mus reveiled little of note. The ganghon cells of the pullidium showed changes and the strutum presented a more severe diffuse parenchanial degeneration. Here as through the entire central nervous system the vessels were markedly dilated (Fig. 4). The subcortex showed distended lymphatic permissionary spices and rare permissionary infiltration. In contrast to the first case the cortex presented quite a good ganghon cell appearance. Here two types of mathology were noted.

Here two types of pathology were noted
Firstly Scars of distinctly long duration were there
The left temporal lole vicinity of the macroscopically
found shell fragment was characteristically altered
After removal of the foreign lody a cavitation in the
cortex surroinfield by a strong flail reaction with con-

Streatum Diffuse preschynal degeneration (g) di lated blood ressels with distended perceasular spice (x) Lacuole formation. Nissl stain

siderable iron containing pigment remained and formed at the loundary to the sulcortex a thick clind will lin the cells of amnoiss horn a degenerated focus was noted. Older searred points of cortical disintegration were found in other parts of the temporal and frontial lolgs with occasional caleified ganghon cells (Fig. 5).

Secondly In the cortex especially in the occupital temporal post central garns and in the frontal lobe were seen frequent small fresh hemorrhages with widened vessels and envilances (lag 6)

In isolated portions of the cortex confined to the 6th and 7th ganglion layers were seen distinct protoplasmic glas productation slight perivascular infiltration and marked gaughon cell changes

Comment Again we have an acute epidemic encephalitis in an individual who had a previous eramal injury. Here however the traum was

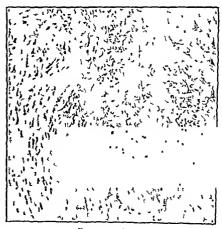

FIGURE 5 CASE 2

I rontal certex Old degenerated area eith calcified

Janglion cells Nissl stam

Post Rolandic cortex. The lines point to fresh hemorrhages in lamina III. Nissl stain.

of seven years duration. The long interval between the war trauma and the onset of encephalitis would ordinarily be considered sufficient ground for disregarding the trauma entuely as in any way concerned in the final fatal illness. The persistence of headache throughout the intervening period, the microscopic findings of old and new lesions, and the dilated blood vessels and lymph spaces, make it necessary that the trauma be regarded as having facilitated the entrance of the later infection into the central nervous system.

Case III. Acute epidemic encephalitis coming on several days after a mild cerebral concussion.

S. S., on April 18th, 1920, a middle-aged salesman, while traveling in a sleeping car, struck his head against the berth. He was briefly stunned. The following morning his actions were peculiar and he felt queer. Several days later there occurred severe headache, pain in the left shoulder, and general malaise. Examination then revealed the presence of temperature, diplopia, facial asymmetry and extreme drowziness. The diagnosis of encephalitis lethargica was then made. Later a typical parkinsonian picture ensued.

Comment: Again a typical clinical picture of epidemic encephalitis, this time with an apparently mild injury to the head a few days prior to the acute onset of the illness. But the fact that he was stunned contradicts the apparent mildness of the injury. A fracture of the skull without concussion may produce less intracranial involvement than a so-called mild concussion. One may visualize in this man a latent infection, and its entrance into the central nervous system made possible by widened blood vessels resulting from the concussion.

Case II'. An acute epidemic encephalitic picture occur, ug three weeks following an injury to the head.

J. D., on December 29th, 1918, this 32-year-old man

struck the back of his head against a desk. He apparently continued at his usual work, but thereafter complained constantly of headaches, was irritable and cranky, and his wife and fellow employees stated that he was not the same man mentally. Eighteen days later, January 16th, 1919, he became acutely ill, was considered a case of influenza, and when he became worse and stuporous was admitted to Bellevne Hospital. He presented a varying stupor from which he could be easily aroused. The cyclids were incompletely ptosed, pupils were innequal and reacted sluggishly, upward and downward gaze was impaired, the facies were like those of an advanced myasthenia gravis, and there was marked muscular rigidity. Because the observers had seen no other cases of encephalitis, and in view of the history of a head trauma, he was diagnosed as a fracture at the base. When Dr. Foster Kennedy saw him, he was impressed by the unusual clinical picture and could not fit it into that of a skull fracture. Later, he made the diagnosis of encephalitis lethargica.

Comment: This case is of extreme interest, as having been one of the earliest seen in this country. The relationship of the trauma to the encephalitic picture occasioned considerable controversy. Irrespective of opinions expressed at the time, our analysis now must take in the criteria of the present paper. Though there is no mention made of symptoms suggesting a concussion, such as loss of consciousness, or of having been stunned or dazed, the fact that he worked steadily despite continuous persistent headache would indicate that he was an individual who would minimize an injury so long as it did not incapacitate him. If so, a transitory dazed period would not be emphasized. That he had a concussion would also seem likely from the testimony of the wife and fellow employees who noticed that he became irritable, and was a changed person. It is evident, therefore, that here again, we have a case of a trauma to the head with cerebral concussion preparing the central nervous system for the entrance of the acute infection.

Case V. A case of acute epidemic encephalitis with recovery, no symptoms for twenty months, and development of a parkinsonian syndrome after injury to the head.

F. D., in January, 1920, a twenty-year-old male was observed at Bellevue Hospital, where he presented a violent dyskinesia of the extremities, had ocular signs, was drowsy, and the diagnosis was encephalitis, chorec form. After discharge from the hospital one month later, he was apparently well for twenty months. In November, 1921, a heavy case fell fifteen feet striking him on the left side of the face and body. He was dazed for fifteen minutes and bled from the nose. Two days later a tremor developed in the left hand. From that time on he gradually developed a complete parkinsonian syndrome.

Comment: A parkinsonian syndrome is a frequent sequel or residual of epidemic encephalitis. Nevertheless, every acute case is not followed by such a chronic course. The injury to the head, with a cerebral concussion, may here be considered as having activated a latent pathological process or possibly hastened the development of the parkinsonian syndrome.

Case VI Acut, epidemic encephalitis occurring eight months ofter o frocture of the pelvis and mijnry to the testicles

D G On May 4, 1920, this 23 year-old mile fell from a roof to a fire escape. He sustained an injury to the testicles and a fracture of the pilvis. There was no loss of consciousness. After several months' treatment he returned to lus regular work. Eight months later, Lebriary 21, 1921, he was admitted to Bellevue Hospital with insomin was confused, irritioue restless, and at times stuporous and somiolent. On exminiation there was strabishies of the right eye, unequal pipplis and masked facies. He remained three days, was observed again for seven days in March 1921, and when exmined in October 1922, laid misal speech biliteral external rectus werkness and the eyes stared. A definite diagnosis of epidemic encephalitis was made without difficulty.

Comment This patient did not sustain any injury to the head and there was nothing in the history to suggest the possibility of cerebral concussion. The acute illness that developed after many months was an independent infection, and the trauma may be channed as an etiological factor.

Cose VII On the doy of the onset of an ocute epidemic encephalitis the left forcarm is sprained

W W On April 9, 1924 this man pulled a belt and sprained the left foreign. He continued working. That creming he became drowsy and saw double. The next day he had headache and fever. This continued for ten days. The dramous of epidemic encephalitis was undeat Post Graduate Hospital where he was later observed.

Comment How a sprain to the forearm can he regarded as related to an acute infection of the central nervous system is difficult to understand. This case is cited, however, for controversies in just such cases are not uncommon. In the absence of any skull injury or concussion, the writer feels that the forearm injury may be ruled out from consideration as a factor in the encephalitic picture.

Case VIII Acute epidemic encephalitis occurring two months ofter injuries to the shoulder and knee

S I A 39 year old min on January 5 1923 fell from a wagon sustaining injuries to the left shoulder and right knee. There was no liead injury and no in terription of consciousness. He was treated at a physician soffice for two weeks. Two months later, March 10th he had a 'cold' which persisted five drys. Eight drys later, March 23rd he was admitted to Gouverneur Hospital with a history of diplopa for three drys, put pils irregular, reacting to light and accommodation and there was vertical instagnius. He was confused disoriented and talkative. He became comatose and died March 25 1923. The hospital diagnosis was encephalitis lethargica.

Comment Here again the injuries were to the extremities and were not associated with any eramal symptoms. In conformity to the criteria of this communication, such injuries play no part in a later developing acute epidenic enceptiolitis.

Case IA Two days after occurrence of pain in the lower lack there ensues an extensive ce tral nervous system disorder diagnased as epidenne encephalitis

I G On November 13 1923, while lifting a barrel this man's left foot shipped and he felt somethings may in the fower part of the back. Two days lifer there developed a paralysis of the right side of the face, and workness in both lower and the right inper extremities. For one month there was fever and he was delirious. At traces he saw double. Examination revealed inhibit to close either eye. The right pupil was larger than the left, motor innervation was impured on both sides of the face, and taste was absent in the anterior two thirds of the toigne. The facies were regarded as typical of paralysis agitans and the draghosis made was encephalists lethargica.

Comment Here we have an acute onset of cranial nerve involvement plus motor weakness in the upper and lower extremities. In the absence of any cranial injury or of cerebral concussion, the lustory of the snap in the brek may be disregarded as participating in the production of the central nervous system affection.

SUMMARY AND CONCLUSIONS

A series of cases with a clinical picture of epidemic eucephalitis is presented, in whom the chief interest is a history of trauma. An effort to determine what effect such traumita may have on this disease is attempted. Cases are presented in which the trauma plays an important role in the production of epidemic encephalitis, and similarly, other cases where the trauma is simply a concidental or chance occurrence. To facilitate analysis of the problems encountered, four questions are presented, and as conclusions are here answered.

1 Following an injury to the head in which there is present evidences of intracranial involvement, the minimal degree being a cerebral concussion, a later developing epidemic encephalitis syndrome must be regarded as having been influenced in its production by the trauma

2 A patient who has had an acute epidemic encephalitis may have chronic manifestations, such as Parkinsonism, initiated or produced by an injury to the head. Such an injury must be severe enough to produce at least the picture of cerebral concussion.

3 A partial clinical evidence of chronic encephalitis such as a tremor of the haud, loss of associated movements, etc. may be regarded as indicative of the full syndrome developing. If such an individual then has an injury, the advance in symptoms is not attributable to the training

4 An injury to any part of the body excepting the skull, particularly when not associated with cerebral concussion signs, plays no role in any part of the clinical course of epidenuc encephalitis.

MORTALITY IN 985 CASES OF DIABETES MELLITUS

By JOSEPH HAJEK, M.D., NEW YORK, N. Y.

From the Medical and Surgical Wards of St. Luke's Hospital, New York City.

N 1926 we reported upon the mortality in 276 cases of diabetes in the Wards of St. Luke's Hospital, with special reference to diabetic coma and infection. The patients were divided into two groups: Group I. composed of 113 cases treated during the years 1920 and 1921, that is before the discovery of insulin. Group II. was made up of 163 cases admitted to the wards in 1923 and 1924, after the discovery of insulin. The year 1922 was intentionally omitted as the amount of available insulin was very small.

Up to and inclusive of 1930, 709 additional cases were collected so that our postinsulin series now comprises 872 cases. It is noteworthy that the general mortality during the early postinsulin period 1923-1924 is almost exactly the same as that of the entire group 1923-1930 inclusive. During the postinsulin period 1923-1924, 163 cases were treated, of these 20 died giving a 12% mortality. Comparing this with the postinsulin period 1923-1930, 872 cases were under observation, 101 of which died with a mortality of 11.6%. though there has been no change in the death rate of the early and later postinsulin years, the general diabetic mortality in our hospital has, nevertheless, decreased 7% over that of the preinsulin years.

The report of the Board of Health of New York City* on the other hand shows a marked increase in mortality in diabetes from year to year during the past ten years.

"Throughout the United States the death rate from diabetes is increasing. In New York

* Frissell, L. F., and Hajek, J., J. A. M. A., June 19, 1926, Vol. 86, p. 1903.

City this disease now causes over 1,900 deaths annually, and this despite the fact that the prevention and treatment of diabetes is well understood. The diabetes death rate in this city is about 50 per cent higher than it was only twenty years ago. Most of the deaths are in persons over fifty years of age, and among these there are twice as many victims among women as among men. Following is the record for the past ten years:"

TABLE 1. DIABETES, DEATHS AND DEATH RATE PER 100,000

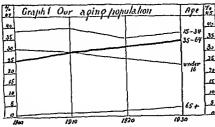

Year	Deaths	Rate	Year	Deaths	Rate
1922	1,448	24.4	1927	1,461	22.2
1923	1,360	22.4	1928	1,663	24.8
1924	1,177	19.0	1929	1,726	25.3
1925	1,313	20.8	1930	1,784	25.6
1926	1,485	23.0	1931	1,921	27.1

Since diabetes most frequently occurs in people past middle life, this increase in mortality can not be explained and may only partly be accounted for by the larger number of persons attaining to 34 years of age and over as shown in Graph 1. compiled from figures in the "Weekly Bulletin."**

The diminution in mortality at St. Luke's Hospital is considered in this paper with reference to coma, hypoglycemia, arteriosclerosis, infection, surgery, age and sex.

Coma: Our decrease of 7% in general mortality is entirely accounted for by the 10%

^{**} Wynne, S. W., Weekly Bulletin, Department of Health, City of New York, January 9, 1932.

GRAPH 1 Percentage of population by age groups

diminution in deaths due to coma Banting's discovery of insulin has taught us to treat diabetic coma and any diminution of mortality in diabetes at St. Luke's Hospital is due to that cause. In the premsulin period almost all of our coma cases died, while in the postinsulin cra out of 21 individual coma cases treated during the past 8 years only 057% It would appear, therefore, that while our diabetics seldom now die of coma their life is, nevertheless, taken from them by an intercurrent disease, of which arteriosclerosis and infection stand as the chief offenders may be argued from the foregoing statement that since the discovery of insulin the life of the adult diabetic has been prolonged. However, according to our figures the average age at death in the premsulin period was 55 years and remains the same for the postinsulin In the early postinsulin period, coma was for the first time in the history of the disease successfully compated. In the later postinsulin years the prevention of coma is practiced with gratifying results. Already we see coma due to diabetes 4 times less frequently than we did in the pre-Banting period The time is not far off when the occurrence of diabetic coma will be as infrequent as death due to coma is at present. It is much easier to prevent coma than to cure it With the development of hospital and clinics for diabetic patients early diagnosis and treatment are made possible. The widespread knowledge of the disease and its dietary management with or without insulin are factors contributing to the diminution and elimination of coma The complete cooperation of the general wards of the hospital with the diabetic clinic Social Service training of the is essential patient completes his educational cycle. Thus patients referred to the hospital from the clinic seldom show anything more than moderate Letosis

In connection with the early diagnosis of diabetes the problem of differential diagnosis between coma due to hypoglycemia coma due to ketosis, and come due to other diseases

comes up and should be stressed. The following illustrative case may be mentioned. A patient, who had long suffered from diabetes was found on the street unconscious. She was brought into a hospital, where it was assumed that she was in diabetic coma. Insulin was administered. It was soon found, however, after examination of the blood that the patient was thrown into severe hypoglycemia (hypoglycemic angina?*) and that her original state of unconsciousness was due to coronary thrombosis.

Hypoglycemia We had no deaths the cause of which could be ascribed to hypoglycemia but its effect causes much morbidity even if of short duration. I have yet to see a patient taking insulin for any length of time who sooner or later does not have an attack of hypoglycemia or of what he takes to be hypoglycemia We educate our insulin cases and rightly so to watch for the symptoms indicative of this condition and impress upon them the proper measures to be taken to overcome it. Nevertheless, it must be difficult for the patient accurately to interpret the onset of the symptoms which at their very beginning are puzzling to say the least. If the patient is an adult whose insulin career is comparatively recent, he will immediately take steps to combat the symptoms whether his interpretation is correct or not If the symptoms clear up, he assumes that his actions were proper. on the other hand, in spite of precaution the symptoms persist, his mind is assailed with doubts, and the physician's help is then required Contrarily, if the patient is a child the first symptoms of hypoglycemia are most frequently overlooked and treatment is begun when severe reaction sets in So that no matter how painstaking our theoretical education of the insulin patient may be, it is, nevertheless his own personal experience with hypoglycemia which helps him most. One or two attacks successfully treated by the patient himself give him confidence and set his mind at rest. It is during this period, according to my experience, in the career of the diabetic that severe reactions are most frequently met "Familiarity breeds contempt" vs at la

Does hypoglycemia or its repeated attacks cause any damage? The effect upon children and young adults remains problematical. In the diabetic past middle life the situation is more complicated. At this time cardiorenal and circulatory diseases are met with, and hypoglycemia may at times add sufficient shock to complicate an already serious condition. I am especially referring to cases falling into the group of coronary scierosis and cardiac insufficiency. In this group of patients

^{*} Joslin E P J A M A August 29, 1931 Vol 97

an attack of hypoglycemia may have disastrous effects upon the heart in precipitating what Dr. Joslin refers to as hypoglycemic angina. Strict prevention of this condition is The difficulties indicated and attempted. under which the patient has to labor in such circumstances are obvious. The initial symptoms are often most perplexing and the best thing the patient can do is to treat all such symptoms as hypoglycemia until proven otherwise. Such procedure, however, is followed invariably by hyperglycemia and glycosuria, and possibly ketosis, if the patient's interpretation was incorrect. In children the initial symptoms of hypoglycemia are easily overlooked and when finally discovered so that preventive measures may be taken the little patient may be in convulsions. In connection with this statement the case of little D. S. may be cited. This boy is 10 years old and has had diabetes for the past 8 years. He had several admissions to St. Luke's Hospital and was seen by Dr. Joslin in his New England Deaconess Hospital. He has had at least 8 severe attacks of hypoglycemia with convulsions and coma as well as many milder attacks; this in spite of the fact that his mother is exceptionally intelligent and in a sense a specialist in diabetes. The boy is bright, cooperative, and honest. He is a moderately severe diabetic (taking about 30 units of insulin per day), who within 24 hours may pass through the symptoms of hyperglycemia, ketosis, and hypoglycemia. Because of this he is rather difficult to manage. It is easier to treat hypoglycemia than to prevent it, which should certainly be the other way around, but the prevention of hypoglycemia must not be at the expense of insulin.

	MORTALITY	
	% in 22 Deaths	% in 113 Cases
In 6 death was due to Cardiorenal Disease and Arteriosclerosis In 4 death was due to Infection In 12 death was due to Coma	28 18 54	5.31 3.54 10.15
GENERAL MORTALITY		19.00

Table 2. Analysis of the Causes of 22 Deaths in 113 Cases, Years 1920–1921.

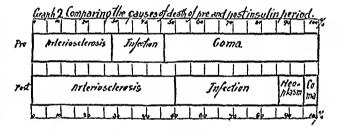

Arteriosclerosis and Infection: These two diseases continue to take a heavy toll of our diabetic patients. This field is largely unexplored and prevention remains the best insurance for these patients. Frequent periodic health surveys in addition to the proper management of diabetes is even of greater importance to the diabetic than to the non-diabetic. Much is accomplished in this direction, but nevertheless, cardiorenal disease, arteriosclero-

sis, and infection account for 86% of our diabetic mortality as may be seen from Tables 2 and 3.

	MORTALITY	
	% in 101 Deaths	% in 872 Cases
In 51 death was due to Cardiorenal Disease and Arteriosclerosis	50	5.85
In 36 death was due to Infection		4.15
In 9 death was due to Malignancy In 5 death was due to Coma		1.03
In 5 death was due to Coma		0.57
GENERAL MORTALITY		11.60

Table 3. Analysis of the Causes of 101 Deaths in 872 Cases, Years 1923-1930

The above figures indicate that the percentages of deaths in the diabetic caused by cardiorenal disease, arteriosclerosis, and infection have almost doubled in the postinsulin period, while deaths due to coma decreased tenfold. This is shown to better advantage in the following Graph 2.

The diminution in general mortality at St. Luke's Hospital in the postinsulin period is shown in Graph 3. This clearly shows that the decrease of 7.4% in our general mortality is entirely accounted for by the 10% diminution in deaths due to coma.

From the above graph may also be seen a moderate increase in mortality caused by arteriosclerosis, infection and malignancy during the postinsulin period. This increase may be accounted for by the great reduction in deaths due to coma, the more widespread diagnosis of diabetes, and by the increase in the number of people living during middle life.

Surgery: Three out of every ten diabetics admitted to St. Luke's Hospital have a surgical condition necessitating an operation.

The surgical postinsulin group 1923-1930 comprises 257 cases with a mortality of 163%, a decrease of 50% as compared with the Pre-Banting period.

Age The mortality as to age was greatest between 41-70 years as may be seen in Table 4, with less cases under 40 than above 71.

Age	Number of Cases	Age	Number of Cases
up to 20	5	51-60	39
20-40	7	61-70	34
41-50	23	71 up	15

TABLE 4. AVERAGE AGE AT DEATH

Set In 1916 Osler gave the sex ratio of male to female diabetics as 3 2 In 1931 Dr Joshin* states "the proportion of males had decreased to 44% in contrast to 47% in 1921 and 55% a decade before" At St Luke's Hospital the proportion of males has increased

. Joslin, E F. J A M A, August 29, 1931, Vol 97, p 591

from 44% in 1920 to 49% during the postinsulin period up to 1931. The mortality sex ratio closely approximates the living sex ratio. The redistribution of sex is significant because it has taken place within the short space of two decades.

SUMMARY

- i The mortality in 827 cases at St Luke's Hospital decreased 7% as compared with 50% increase reported by the Board of Health, NYC
- 2 The decrease is entirely accounted for by
- 3 A redistribution of the causes of death is taking place. While deaths due to come diminished tenfold, those caused by cardio renal discase, arteriosclerous and infection have doubled.
- 4 Surgical mortality in the diabetic at St Luke's Hospital decreased 50%
- 5 Neoplasm as a cause of death is on the increase in the diabetic individual
- 6 The average length of life of the adult diabetic has not as yet been prolonged by insulin

THE ROLE OF CHILD GUIDANCE IN THE PREVENTION OF SCHIZOPHRENIA (DEMENTIA PRAECOX)

By H, L LEVIN, M D, BUFFALO, N Y

From the department of Clinical Psychiatry Buffalo State Hospital Buffalo, N Y Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo N Y, May 24 1932

EMENTIA praecox, or schizophrema according to the U.S. Census, incapacitates more individuals in this country than does cancer or tuberculosis. In point of the number involved, schizophrenia is thus the largest single medical problem of the day, and any procedure that holds forth promise of prevention or arrest or cure, if only in a comparatively small percentage of cases, is worthy of our serious atten-While the writer freely admits that we have not as yet gained a full and complete understanding of the various factors which bring about this illness, he holds that at present the etiologic theory that offers the best perspective for action, from both the preventive and curative viewpoint, the so-called "psycho biologic" theory formulated by Adolph Meyer in 19061 According to this theory, the manifestations of schizophrenia arise on the basis of a special temperamental make-up or personality, and the symptoms may be regarded as the natural development of faulty habits of reactions (or ways of feeling, thinking and acting), cultivated by the patient from his earliest years and fostered both by hereditary factors and faulty environment. These oddities in thought and behavior have been included by some authors under the general term of "shut-in personalities "2" One recent text-book3 describes five types of "shit in personalities"

(a) The "madequate" type of child, who is not feeble-minded, but he is entirely lacking in ambition and does not make use of his intellectual or physical powers He has no hobbies, no likes or dislikes Rewards or punishments mean little to him. He may play truant, but the truancy is not motivated by the desire to carry water to the circus elephants or to attend a baseball game These hours of freedom, gained through his truancy, are wasted in utter idleness or aimless wandering about (b) The "precocious" type has a brilliant intellect. He is serious, scholarly, and a model student. He usually captures most of the prizes for academic work, but his entire life is sharply circumscribed by his books and his studies The social life of his school, and often of his own family, means absolutely nothing to him He never takes the initiative in forming a friendship and responds only half-heartedly if others take the initiative (c) The third, is the neurotic type of child He escapes his responsibilities and unpleasant ditties by complaints of headaches and various other bodily ailments. He to always selfish and often tries to "get by" with the aid of deceit or temper transrums (d) The

fourth is the "day-dreamer." His chief occupation is day-dreaming. He shuns his companions with their adventures and heroics of the playground, but instead loses himself in phantasies or indulges himself in a play life peculiarly his own. (e) Finally there is the "juvenile" type. This child never grows up emotionally. He remains tied to the proverbial mother's apron strings. He becomes hopelessly homesick when taken away from home. He never enlarges his friendship beyond his own immediate family circle. He evades responsibility, but is forever seeking parental approval and protection.

Where the parents or others have been capable observers and are sufficiently co-operative to tell all they know, a history of these faulty habitual reactions in childhood can be obtained in a large proportion of the cases of adolescent or adult praecoxes who are committed to state hospitals. Four such cases are described below from the records of a state hospital, illustrating Meyer's conception that the psychotic symptoms necessitating commitment to State Hospitals are but natural outgrowths of faulty reaction habits of childhood. These are followed by the case records of four children treated at Child Guidance Clinics for abnormalities in mood and conduct strikingly similar to those of the committed adults, and treated with apparent success for two to four year periods.

Case I illustrates the juvenile type of shut-in personality.

John B. (No. 19644) was admitted to a State Hospital at the age of 25 because he broke dishes and furniture in his mother's home apparently in reaction to the delusion that he was being talked about and laughed at by practically every one who came in contact with him. His mother stated that his psychosis really began about two years previously when he fell in love with a girl and she would have nothing to do with him. From the mother we learn also that he had been showing abnormal conduct from early childhood in response to an equally abnormal home environment. At the time of his birth, his mother was suffering great mental anguish due to his father's excessive alcoholism and abusiveness. Because of this, his mother broke up the home when the patient was four, and she returned to her parent's with the patient. She apparently lived her emotional life through her son, and he in turn became intensely jealous of her. If a stranger showed any attention to her, he would often respond by temper tantrums. If he sensed that she was to go out to a social affair with any man, it brought forth the same response. He would allow no one to fondle him except his mother. He slept with his mother until he was thirteen. At about that time, as so often happens with extreme or unhealthy attachments, the emotion changed from its positive to its negative phase. Hence, from insisting upon

sleeping with his mother, at the age of 13, we find him at the age of 14 in an Industrial School because he repeatedly ran away from home and his wanderlust persisted until his admission to a Without going into the State Hospital at 25. deeper psychoanalytic implications, is it too farfetched to say that his psychotic reactions to the love situation at 23 were distorted by the pattern laid down when he attempted to monopolize his mother's affection at 13. And are we unreasonably optimistic if we surmise that psychiatric interference in his early childhood might have produced the beneficient modification both in the patient's environment and in his conduct that are described in a parallel case quoted below (Case V) from the records of a Child Guidance Clinic?

Case II (F. D. O. No. 17312) illustrated the precocious type of shut-in personality. She was committed to a State Hospital at the age of 34 because she insisted upon going about the streets attempting to convert strangers and making an unbearable nuisance of herself by calling on priests at unreasonable hours. Early in her childhood the family circumstances were such that outside of school hours her time was entirely taken up with helping her father in his store and her mother with the care of the younger children. She had practically no play life and formed no girl or boy friendships. However, she seemed to be entirely satisfied with her lot, particularly inasmuch as she was precocious in school, doing substitute teaching as early as her 13th year. Later she took up office work and became intensely interested in the business affairs of her employers, accepting extra duties and responsibilities with such cheerfulness that her co-workers thought her queer. This attitude toward her was further enhanced by the fact that she studiously avoided all opportunities for social contacts. Aside from her work, the only other interest she had was her church and as time went on her religious activities began to assume an impractical intensity. At about the age of 31 she gave up office work and accepted a teaching position in a Parochial School. After several months she became dissatisfied and entered a training school for nurses. Soon after that her religious activities began to assume a psychotic tinge.

With the knowledge that the modern psychiatrist has of the Oedipus (or Electra) situation and its potentialities for good or ill, one wonders whether her abnormally inflated desire to serve her physical, spiritual and business fathers could not have been socialized sufficiently, if dealt with during her childhood or early adolescence, and thus ward off her psychosis and save to society an intelligent and efficient worker.

Case III is a good example of the neurotic type. Mabel (No. 22653) at the age or 21, claimed she was entirely too weak to work, and when

she forced herself to take a job she soon was obliged to give it up because of peculiar confused spells She grew more and more apathetic, but nevertheless an attempt at suicide precipitated her voluntary admission to a State Hospital Physical examination did not disclose any foundation for her subjective sensations of exhaustion and confusion A perusal of her childhood history, however, discloses that at the age of ten she had an attack of measles from which she made a good recovery However, hecruse of the time she lost from school, she found it difficult to maintain her former high standing in her class and therenpon began to lose interest in her school work and began to complain of various bodily ailments and used these as excuses for further abscences from Being the youngest of five, her parents school indulged her and allowed her to continue along this path of least resistance so that she lost about four years of schooling From that time on she continued to react to difficult situations in the same pathological way. This case essentially has the same factors as the case of David (Case No VI) quoted below, whose withdrawal from reality followed two attacks of pneumoma and one wonders whether Mabel might not have suc ceeded in reclaiming herself, as did David, had she attended a Child Guidance Chinc

Case IV The Day-Dreamer type (F L No 17401)

Committed to a State Hospital at the age of 41 She talked of her mother and older sister ruling her and the entire world by "evil power," and her commitment was precipitated by the fact that she created a disturbance while attending church in reaction, apparently, to her hallucinating nude priests and worshippers. Even to the most rabid anti-freudian it should become apparent that there 17 some connection between the delusion at 41 that mother has an evil power over the patient. and the circumstance related by the mother that throughout her childhood the patient maintained a very irritable, stubborn and refractory attitude toward her mother, whereas the other children were quite obedient. Although she possessed normil intelligence, she was backward in school apparently because she was given to day-dreaming At home also she kept away from the other children During a certain portion of her childhood she was extremely fond of sechiding herself in her room and indulging in peculiar pliantasies of a religious inture Had there been a Child Guidance Chine which she could have attended some thirty years prior to her psychosis it would have been brought out then (as it was thirty years later) that there was almost constant wrangling between the parents, that our patient was de-cidedly an "unwanted child" and that whereas her mother was unduly severe her father was equally indulgent. Perhaps if a Child Guidance set up had been successful in establishing a more

normal emotional atmosphere in that home during the patient's early childhood, she would have avoided a psychosis, as have her brothers

The following four case records are from the Child Guidance Chine by Dr. Donald W Cohen Asst. Psychiatrist, New York State Department of Mental Hygiene, and I herewith express my appreciation of his generous co operation

Case V. Joseph, aged 14, referred to the clinic by the nurse in his school because of his peculiar conduct This peculiarity manifested itself chefly in the form of avoidance of others, temper outbursts, and a marked antagonism for his brother who was three years his jumor family history brought out the facts that both parents were unstable individuals The father. who deserted the family when Joseph was 21/2 years old (just prior to the birth of his younger brother), was described as being an irresponsible. madequate type of man who never earned enough to support his family He was strongly interested or hypnotism and mental telepathy The mother when about thirteen or fourteen years old suffered nervous breakdown and had to leave school for She easily became excited and two years nervous when faced with difficulties and she realized that she probably had not provided as good training for her children as she might have. She had supported the family by dressmaking since her husband's desertion. Up until the birth of the younger boy she had centered all her attention upon Joseph From Joseph's personal history it was learned that as a child he was not strong physically, that enuresis occurred until he was four years old, that at the age of seven he had what mother described as an "intestinal upset" and which was accompanied by high temperature for three days After this attack he was unable to walk but doctors stated he was not paralyzed Gradually he began to walk again, but for several years was clumsy in his movements He has always had a strong dislike for physical exercises and activity of any kind. As a very young child he played by himself with his toys, never seeking the companionship of others Frequently he would wander away from his home When first seen at the chinc he was in first year lugh school Throughout his school years he had little or nothing to do with the other pupils and remained by himself. It was during the few months prior to the initial psychiatric examination that he actually began going out of his way to avoid people, becoming irritable, and subject to temper outbursts when forced into contact with The younger brother who was interviewed at clinic was definitely the opposite type, an out and out extravert He realized Joseph was "different" and constantly made him the butt of his tokes and the subject of his teasing in which he seemed to take almost fiendish delight Joseph's only interests seem to be his school work in which

fourth is the "day-dreamer." His chief occupation is day-dreaming. He shuns his companions with their adventures and heroics of the playground, but instead loses himself in phantasies or indulges himself in a play life peculiarly his own. (e) Finally there is the "juvenile" type. This child never grows up emotionally. He remains tied to the proverbial mother's apron strings. He becomes hopelessly homesick when taken away from home. He never enlarges his friendship beyond his own immediate family circle. He evades responsibility, but is forever seeking parental approval and protection.

Where the parents or others have been capable observers and are sufficiently co-operative to tell all they know, a history of these faulty habitual reactions in childhood can be obtained in a large proportion of the cases of adolescent or adult praecoxes who are committed to state hospitals. Four such cases are described below from the records of a state hospital, illustrating Meyer's conception that the psychotic symptoms necessitating commitment to State Hospitals are but natural outgrowths of faulty reaction habits of childhood. These are followed by the case records of four children treated at Child Guidance Clinics for abnormalities in mood and conduct strikingly similar to those of the committed adults, and treated with apparent success for two to four year periods.

Case I illustrates the juvenile type of shut-in personality.

John B. (No. 19644) was admitted to a State Hospital at the age of 25 because he broke dishes and furniture in his mother's home apparently in reaction to the delusion that he was being talked about and laughed at by practically every one who came in contact with him. His mother stated that his psychosis really began about two years previously when he fell in love with a girl and she would have nothing to do with him. From the mother we learn also that he had been showing abnormal conduct from early childhood in response to an equally abnormal home environment. At the time of his birth, his mother was suffering great mental anguish due to his father's excessive alcoholism and abusiveness. Because of this, his mother broke up the home when the patient was four, and she returned to her parent's with the patient. She apparently lived her emotional life through her son, and he in turn became intensely jealous of her. If a stranger showed any attention to her, he would often respond by temper tantrums. If he sensed that she was to go out to a social affair with any man, it brought forth the same response. He would allow no one to fondle him except his mother. He slept with his mother until he was thirteen. At about that time, as so often happens with extreme or unhealthy attachments, the emotion changed from its positive to its negative phase. Hence, from insisting upon

sleeping with his mother, at the age of 13, we find him at the age of 14 in an Industrial School because he repeatedly ran away from home and his wanderlust persisted until his admission to a State Hospital at 25. Without going into the deeper psychoanalytic implications, is it too farfetched to say that his psychotic reactions to the love situation at 23 were distorted by the pattern laid down when he attempted to monopolize his mother's affection at 13. And are we unreasonably optimistic if we surmise that psychiatric interference in his early childhood might have produced the beneficient modification both in the patient's environment and in his conduct that are described in a parallel case quoted below (Case V) from the records of a Child Guidance Clinic?

Case II (F. D. O. No. 17312) illustrated the precocious type of shut-in personality. She was committed to a State Hospital at the age of 34 because she insisted upon going about the streets attempting to convert strangers and making an unbearable nuisance of herself by calling on priests at unreasonable hours. Early in her childhood the family circumstances were such that outside of school hours her time was entirely taken up with helping her father in his store and her mother with the care of the younger children. She had practically no play life and formed no girl or boy friendships. However, she seemed to be entirely satisfied with her lot, particularly inasmuch as she was precocious in school, doing substitute teaching as early as her 13th year. Later she took up office work and became intensely interested in the business affairs of her employers, accepting extra duties and responsibilities with such cheerfulness that her co-workers thought her queer. This attitude toward her was further enhanced by the fact that she studiously avoided all opportunities for social contacts. Aside from her work, the only other interest she had was her church and as time went on her religious activities began to assume an impractical intensity. At about the age of 31 she gave up office work and accepted a teaching position in a Parochial School. After several months she became dissatisfied and entered a training school for nurses. Soon after that her religious activities began to assume a psychotic tinge.

With the knowledge that the modern psychiatrist has of the Oedipus (or Electra) situation and its potentialities for good or ill, one wonders whether her abnormally inflated desire to serve her physical, spiritual and business fathers could not have been socialized sufficiently, if dealt with during her childhood or early adolescence, and thus ward off her psychosis and save to society an intelligent and efficient worker.

Case III is a good example of the neurotic type. Mabel (No. 22653) at the age or 21, claimed she was entirely too weak to work, and when

aminer when spoken to. When asked a question he had to be niged to reply and his answers were very brief, one to two words in length. quently, instead of answering, he would shake his head in the affirmative or negative. His emotional response was entirely inadequate. made facial grimaces and gave vent to short outbursts of laughter. He realized school was becoming more difficult for him but he could offer no explanation. He acknowledged his desire to be by himself, rather than with other boys. had had two chums but now seldom had any contact with them. He complained of occasionally hearing noises in his ears that sometimes sounded like human voices, although he has never been able to distinguish any words. Often he would imagine hearing his mother's voice calling him when she was not present. All interest in athletics and boys' games was lost. He realized that he was becoming more irritable than formerly and losing his temper more easily. No definite delusional trends were elicited. In dress and appearance he was quite eareless. His main and only interest appeared to be electricity.

In the Stanford-Binet Psychometric Test he attained a mental age of eleven years, four months and an I. Q. of 78. No great amount of importance was placed on this result as he cooperated poorly and took little interest in the tests.

Physical examination was practically negative save for being about six pounds underweight.

At the conclusion of the initial examination, it appeared doubtful whether this boy would be able in adjust outside of an institution for any length of time. The diagnosis was very evident, an early case of schizophrenia (dementia praecox). However, it was felt that strennous efforts should be made to try and improve his adjustment in his present environment and that hospitalization should be used only as a last resort. With this aim in mind, his case was fully discussed with his mother, teachers, school principal and boys' director of the Y. M. C. A. The cooperation of all was elicited. No ungraded or vocational classes were available, but the teachers were asked to and did give him more individual attention. He was permitted to take two and a half hours ol sliopwork a day. An effort was made to have him join the Boy Sconts but he refused to cooperate and the matter was dropped. He would give no reason for this. His interest in the Boys' Y. M. C. A. was aroused and arrangements were made to give him a membership card for this organization. Both his mother and teachers were instructed to cater to his fondness for electricity, but also to foster an interest in athletics and group activities. It was further advised that he return to clinic at frequent and regular intervals for personal interviews with psychiatrist.

At the end of one year's treatment a marked change was observed in David's condition. His

school work was so improved that he passed eighth grade successfully and was doing good ninth grade work. He now displayed a healthy interest in group activities and competitive sports, having participated actively in baseball, basketball, football and swimming with the other boys in his neighborhood every day after school hours. He became more communicative and responsive. His emotional response was quite adequate. No facial mannerisms or impulsive outbursts of laughter and anger occurred as they had previously. The noises in his ears were something of the past. He appeared happier and brighter and was proud of his scholastic achievements. He expected to enter high school in the next term. He still maintained an interest in electricity. He now was very neat in his personal appearance and took pride in the way he dressed and carried himself,

It would, of conrse, be nawise to state that David lad recovered completely from his abnormal mental condition, or that the present state of the boy will remain as satisfactory as it now is But, at least, the development of the malignant condition has been arrested and modified for some two years and what appeared to be a social and economic liability has been changed into a social and economic asset.

Case VII. Katherine, aged 11, was referred to clinic by her father and teacher because she refused to talk to anyone at home and at school. It was said that she appeared to be normal up until the time she returned from her summer's vacation which was spent with her aunt. When Katherine arrived home she observed that her mother was pregnant. That day she talked incessantly and very peculiarly, her main trend of conversation centering about her having many babies when she was older. A day later Katherine became mute and would talk to no one, and slie had several crying spells. This conduct continued for about three months when she began talking in school. At home, however, she would talk to no one and would become very angry whenever her father went near the baby which had recently been born, or when he was near his wife. Frequently she was caught pinching the baby when she thought no one was observing her. She was never able to get along with the other children at home and often quarreled with them. From the history it was learned that Katherine's mother was an uneducated, ignorant woman, very unstable, usually exacting with the children, abusive towards them, a chronic scold, and frequently given to the use of vile language when dealing with the children. The father, on the other hand was an intelligent, affable, easy-going kind man. extremely solicitons of his children, nelfare, es. pecially Katherine's, who was the steethed and his favorite. Between Kathering and her father a strong bond of attachmen
There was nothing unusual in the personal history of Katherine. At the time of examination Katherine was in fifth grade doing excellent work.

Physical examination was negative.

In the mental examination she cooperated well. She was a bright appearing girl, quiet, friendly, well mannered, and quite willing to discuss freely with the examiner her present difficulties. stated that for as long a time as she could remember she has had a marked antagonism for her mother and a strong attachment for her father. She attributed this to the mother's attitude towards her. She said that mother was constantly scolding her vilely and without reason and that nothing ever suited her. All this Katherine resented strongly. Her father, on the other hand, she stated, was the antithesis of her mother and she loved him dearly. He was always kind towards her, and treated her more like an equal. le seldom scolded her, but when he did she felt ery depressed and unhappy rather than resentful. Then he was at home he spent much time playing ith the children, especially Katherine. She said ne resented somewhat his display of affection wards the other children. When asked why she ad stopped talking, she said it was to get even ith her mother for the latter's conduct towards She felt this would make her mother feel ad and feel sorry for the way she had acted. urthermore, she stated, that if she did not talk ien her mother would not bother her or scold er so much. She would not commit herself as what her attitude towards the other children t home was, especially towards the baby. aid that when she became an adult she wished marry a wealthy man, but one who must be as good as my father." On the psychometric est Katherine attained a mental, age of 13 years nd an intelligence quotient of 116.

In this case we were unquestionably dealing 7th a girl possessing an electra complex in a rarkedly pathological state. It was felt that this xaggerated pathological condition resulted from ne malignant situation at home, the attitude of ne parents, especially the mother. The mother ormally the rival of the girl for the affections f her father had by her attitude and behavior ncouraged the transfer of this rivalry from a passive state into one of active aggressive antagonism and hatred. The girl considered the mother her bitter rival whom she wished to get rid of in order that she, the daughter, could occupy in the home the position that the mother now held. This desire to replace the mother was encouraged by the father's conduct. The father by his display of excessive affection, his oversolicitous and over-protective attitude, was unconsciously encouraging this desire of Katherine's. Her mutism was precipitated by the pregnancy of the mother, for with the birth of another child her security in the home and her close relationship with her father became threatened. Each child meant a stronger bond between mother and father, as well as another one with whom to share the father's affection. Her mutism was an attempt to punish the mother and perhaps also the father for his betrayal. Her inability to get along with the other children and her animosity towards the baby were expressions of her jealousy and her dislike for the affection her father gave them.

It was felt that in treating this problem it was necessary to attack it directly through the father and the girl, in view of the mother's instability and limited intelligence. The dynamics at work in this case relative to the parental attitudes were thoroughly gone into with the father. It was impressed upon him that change in the motherdaughter relationship would have to occur. The mother's continual nagging and fault-finding would have to be replaced by a great show of affection even going so far as to favor her more than the younger ones. Household duties were to be assigned her so as to make her feel she had some part in the running of the household. Her father was also instructed as to the means he should employ in modifying Katherine's strong father fixation. It was explained to Katherine in simple terms just what the psychology of her conduct was, with all its ramifications and inter-relationships between her and the other members of the family. Advice was given her to what procedure she was to follow at home in order that a better adjustment might occur.

The results which occurred in this case, after treatment was instituted, can well be summarized from a few excerpts of a letter received from a local social worker recently, four years after the initial examination. "Mr. R., Katherine's father, can hardly believe that a child could change as They have tried to carry out your recommendations faithfully and certainly have had results. It was really pathetic to hear Mr. R. speak of all that has been done for Katherine. He told me he could never repay you but that he did want you to know how grateful he is. She is adjusting real well and at present is in first year high school, getting grades between 80 and 90 in all subjects. She is greatly interested in Sunday School work and is teaching a good-sized class in the church Sunday School.

Case VIII. Mary, aged 10½, had for a period of about 2½ years been subject to peculiar "spells" in which she appeared to be irrational, cried without apparent cause, complained of feeling dizzy and would fall to the ground in a seemingly unconscious condition. The teacher of the rural school she attended having witnessed some of these attacks referred her to a clinic for study.

The history described the father of Mary as being very alcoholic. When under the influence of drink he became cruel and abusive towards his wife and children. He was of subnormal intel-

hgence, irresponsible, a poor provider, and displayed little affection or interest in any of the members of his family. Because of his conduct congenial family life was unknown in this home. Working only irregularly the twenty acre farm he and his family lived on, the economic status was very poor. The mother, on the other hand, was somewhat of a better and higher class type of individual who cared as best she could for her family and home considering the handicaps of insufficient means, and the behavior of her husband. I requently she had to work for the neighbors to obtain funds for the upkeep of the home. There was no history of any mental or nervous disorder on the paternal or maternal sides of the family.

Nothing significant was observed in Mary's development save the occurrence of a convulsion at the age of five months which was thought by the physician to be due to a gastro intestinal upset Her birth was normal Teething, talking and walking occurred at the usual time. Habit formation was easily established. At the age of nine she had two menstrual periods but none since then. She had just the ordinary diseases of child-At the time of examination she had hood reached third grade and was doing fair school She did not enter school until eight years She was described by her mother and teacher as a fimid, quiet, modest, seclusive, nervous child who frequently displayed stubborn, garrulous tendencies and who easily became discouraged when things became difficult or unpleasant Neither felt she was a happy child

Physical examination of Mary was negative except for enlarged tonsils. During the first interview she cooperated poorly, as it was difficult to get her to talk Frequently, blocking occurred when the subject of her "spells" was mentioned Emotionally, she seemed somewhat depressed She stated that for two or three years she had been having at home and occasionally at school what she called "dizzy spells" During these "spells" she would often fall to the ground and everything would seem confused and mixed up There was no amnesia for events occurring during these episodes, and she was able to hear the voices of the people who were near her at the She had never injured herself in any way during these attacks. After the attack she would feel exhausted but not sleepy. No information could be elicited from her as to what might have precipitated any of the attacks. She stated her affection was centered chiefly on her mother, who was kind and considerate. For her father she had a marked antagonism and hatred The basis for this was his conduct towards her mother and toward herself, his constant drinking and abusiveness and his failure to properly care and provide for his family Frequently, he would whip her severely without any just reason Consequently, she developed a marked fear for him,

especially when he was near her. When asked about the content of her dreams, she stated that repeatedly she would dream of a fierce man carrying her away. After these dreams she would wake up in a state of fear and agitation. The mother also reported that often in her spells she would cry out, 'Mother, take me and the baby away from home.' Mary stated it was because of father's behavior and her fear of him that she was judhappy at home.

In the psychometric examination she attained a mental age of 7½ years and an 1 Q of 71. It was felt, however, that this was not an accurate estimate of her actual intelligence, but that she rated much higher and that this low result was due in large part to the blocking as a result of the mental conflict present.

After the examination was completed the factors underlying and producing Mary's peculiar conduct seemed quite apparent. The "spells' from their description by the mother, teacher and child were typical of the functional or hysterical seizure rather than the actual epileptic type of convul-It was felt that the causes of these attacks were psychological in origin. She had not learned to face reality and difficult situations sult of the unsatisfactory home situation produced by the father's attitude and conduct much mental conflict had developed in the child Faced with what to her were unpleasant and impossible situations she fled from them and sought refuge in these "spells" which simulated periods of uncon-In this way she blotted out difficulties and escaped from them. Here was already being laid the foundation for an actual psychosis of a schizophrenia nature

From the information gathered by the social worker relative to the home conditions and the father whom she interviewed, it was felt that Mary's remaining in her home under present conditions would result not only in a continuation of her maladjustment but that the schizophrenic reactions would become more deep rooted and more malignant With this in mind plans were minde to remove her from her own home and place her m a foster home. Here she would receive proper care and attention as well as some parental affection and be subject to a more normal type of home life rather than a home of conflicting and malignant forces. It was also deemed advisable that she report to chuic at regular intervals for interviews with the psychiatrist in order that the causes and forces producing her past conduct could be explained to her and to help in her ad-It was also arranged to have the **ustment** psychiatric social worker and local workers keep in close contact with Mary as well as her parents The latter was done with the aim of eventually changing the home situation from its past imdesirability to one in which proper adjustment of Mary might later occur.

This program could only partly be carried out, but the results have been most encouraging. She was not placed in a foster home as was recommended, for the cooperation of the Children's Court Judge could not be obtained. Instead, she was placed in the home of a relative, but after a short period she was returned to her parents, as this proved unsatisfactory. With cooperation of the local authorities, the psychiatric social worker and the local social workers attacked the problem of the father directly. He was placed on probation to provide properly for his family and to stop drinking. Efforts were made to give him some insight into Mary's difficulties and the relationship of his conduct to her maladjustment.

Over two years have elapsed since treatment was instituted and changes made in the home situation. There have been no "spells" or attacks of any kind. Mary's timidity has almost entirely disappeared. She does not become discouraged as she did formerly. Now she is happy and cheerful most of the time and quarrels very little with others. No signs of nervousness have been observed. She is helpful at home and interested in group play and outside activities. The father, who has turned over a new leaf, is working industriously, has not been intoxicated, and is aeting towards his family in an affectionate, fatherly manner.

Unquestionably, here was a child headed for a serious mental disorder had there not occurred early recognition of the malignant factors at work and treatment instituted. Not only has a more satisfactory adjustment of the child been accomplished, but, through the treatment of her problem, a better family inter-relationship has been affected.

SUMMARY AND DISCUSSION

The "psycho-biologic" theory formulated by Dr. Adolph Meyer some twenty-five years ago offers, for the time being at least, the best working hypothesis in the attack on schizophrenia, particularly in its incipiency or early stages. A group of four adult dementia praecox cases is cited from the records of a State Hospital illustrating Meyer's conception that the psychotic symptoms of the adult are but the natural development of faulty habits of feeling, thinking and acting cultivated by the patient during his childhood. Likewise four "child problem" eases are cited from the records of a Child Guidance Clinic showing a striking similarity to the adult praecox cases, both as regards the environmental factors and the Although the four problem ave been definitely started on

psychiatric intervention ap-

peared to have vitiated some of the malignant elements in the environment and brought about for a period now of from two to four years, an apparent arrest of the praecox process. The question is raised whether similar intervention during the childhood of the four adult praecox cases might not have been the means of preventing ehronic, if not life long, psychoses.

It is the opinion of the writer that the victory over schizophrenia will not be gained by the discovery of a brilliant bio-chemical or physiological specific, as was the case with diphtheria and typhoid, but rather by a long and tedious educational campaign as in the case of tuberculosis. This entails first the acquisition on the part of the medical profession of a thorough and intimate knowledge of the natural life history of the schizophrenie process from its incipiency in children to its full fledged form in adolescents or adults. Secondly, as in the fight against tuberculosis, the psychiatrist must educate the public, particularly that part of the public which comes in contact with the child, to be "schizophrenically minded." That is to say, the family physician, the nurse, the pediatrician, the educator, the reereational director, the social worker and above all the parent, must be educated up to the idea of reeognizing that certain oddities in childhood conduct may be the forerunners of a severe and chronic mental disease, just as certain physical signs, e.g., eough or loss of weight, may be the first indication of a serious physical disease. And they also must be reconciled to the fact that sometimes the path to mental health is a long and perhaps expensive one leading to radical and costly modifications in the child's environment.

Child Guidance elinics help in the prevention of dementia praeeox in two ways. They deal directly with the individual incipient praecox necessarily only in a small number of cases. But they have a much more potent contribution to offer. They are in a splendid position to amplify our knowledge of the development and the structure of dementia praecox, and they are coming to play the leading rôle in the educational campaign which will enable the family physician, the teacher, the parent and the others mentioned, to attack the praecox problem as frankly and as intelligently as they now are able to do in the case of tuberculosis.

ARE X-RAYS OF VALUE IN THE TREATMENT OF RINGWORM OF THE HANDS AND FEET?

By RICHARD J KELLY, MD, NEW YORK, N Y

From the Laboratory for Medical Mycology and the Department of Dermatology Van Ierbill Clime College of Physicians and Surgeons Columbia University New York Read at the Annual Meeting of the Medical Society of the State of New York at Buffalo N Y May 24 1932

HIS report is presented with the hope of offering some concrete evidence concerning the usefulness of a rays in the treatment of imgworm of the hinds and feet. It is to be un derstood that the purpose here is not to compare the effectiveness of a rays with any definitely proven and accepted fungicides. Rather the undertaking has been prompted by the many discussions concerning the actual therapeitic value of rays in this affection More particularly did this subject arouse favorable and unfavorable comment at the meeting of this section in 1931 and also at the meeting of the American Medicil Association in Philadelphia last year in mind the controversial nature of this subject preparations for this report were begin at the Vanderbilt Clinic in September of 1931, at the suggestion of Doctor George Clinton Andrews The seasonal incidence of the disease as will be explained later, has affected the number of cases treated and likewise has made selection a difficult problem However, anticipating this difficulty at the outset, the following procedure was adopted as constituting the fairest and most unbiased attack on the problem

Each patient at presentation was carefully instructed to use nothing except bring and onthinent on all the affected members. A photograph was taken of the parts involved. Then one affected member was given τ ray treatment (½ crythenia dose infiltered) and the other was given to τ ray treitment, being used as a control. The member chosen for a ray therapy was always the more in volved, where differences in the severity of the involvement were present.

After an interval of one week the patient was again seen, when another photograph was taken of all the involved pirts and ½ crythema dose of a rays was applied to the previously exposed hand or foot. Following the original plan the other member was not treated by r-rays. Another week was allowed to elapse, the patient meanwhile continuing borie acid ontinent locally. At the end of two weeks all the involved parts were once more photographed. No a ray treatment was given at this point.

An initial dise of $\frac{1}{2}$ ed of r rays was used to hasten the interpretation of results rather than being arbitrarily selected as that form most adapt ed to the treatment of ringworm of the hands and feet. Furthermore it was considered that if any improvement from a ray therapy was to seen it should make some appearance after a total of $\frac{1}{2}$ of an exthema dose. Borie acid outment was

used throughout this procedure in the nature of a placeboots reputed functional effect, but being considered of any greater value than that of many other substances of improven ment. The results, to be detailed liter show that the choice of this outnient proved its functional nature in be negligible.

A total of seventy six cases was seen since the beginning of this work. Of these twenty were acceptable for treatment with 1 rays. These were chosen because of their history physical micro scopic and cultural qualities. Every case treated was definitely proven to be positive for fungus microscopically and culturally The majority were new and intreated cases. None had had any a ray therapy applied in any form previously Fire had made local applications of omtments at home with no appreciable curative effects case was acceptable if my form of dermatitis venenata from local treatment was cyidenced. Of the twenty cases subjected to the foregoing form of a ray treatment four were found to be positive for fungus on the hands and feet. Three were positive on the hands with no foot involvement Nine were positive on the feet with no hand involvement and four were positive on the feet with trichophytid on the hand. No discriminations other than these just mentioned were made concerning the physical aspects of the cases treated included objectively scaling, oozing, vesiculation, induration and erythema among the physical features observed at the time of the first visit

As this scheme of treatment was followed, the patients on consecutive visits were questioned concerning chincal progress somewhat as follows. At the date of the hist consultation a careful history of the patients' symptoms was taken ally included complaints of itching, borning, ooz ing reduces and often of small blisters appearing on the hands and feet Variable degrees of se verity in the affected parts were likewise care fully noted. After one week succeeding the application of 1/2 of an erythema dose of 1 rays to one affected member the patient was again seen Questioned at this time concerning the condition of the affected parts the nurform reply was that the member treated with borie acid omtinent was comfortable from twenty four to forty eight hours following the first application during succeeding days with constant use of this medication relief of symptoms did not continue but rather there was a return of the original state of irritation Contrasted to this, the patients stated that the member treated with a rays was

decidedly more comfortable. When reviewed objectively, the offending members showed little or no improvement in that to which the boric acid ointment had been applied while there was obvious benefit to the member treated with x-rays. The patient was instructed at this visit to persist in the use of the boric acid ointment for another week. At the end of two weeks, after 34 of an erythema dose of unfiltered x-rays had been given, the patients were again interviewed. At this time the difference in the condition of the hand or foot exposed to x-ray therapy and that treated only with boric acid ointment was even more accentuated. The untreated member showed no improvement whatever, or negligible amounts of improvement, while the member treated with x-rays was either entirely cured or well on the way to recovery.

It might be added at this point that, where vesicles appeared at the time of presentation on either member, some were opened and others were allowed to remain unopened. This procedure seemed to have made little difference toward recovery, since at the end of two weeks the part treated with boric acid ointment showed numerous recurrent vesicles as well as many new ones. However on the irradiated member, when the sites of the previously unopened vesicles were incised (after x-rays e.d. 34 had been given) the contents of the vesicles had apparently been absorbed and the lesions themselves resolved. Also there were no new vesicles present on this hand or foot.

At the end of three weeks it became necessary to institute x-ray treatment of the previously untreated member because of the discomfort of the patient as well as of his impatience. The results obtained after both hands or feet had been exposed to x-rays not only were satisfactory to the patient but definitely informative to the observer. Because of the apparent beneficial effects of the x-rays in those cases which had not shown a complete clinical cure after 3/4 of an erythema dose, further x-ray therapy was given. The total fractional dosage of x-rays given to any one case did not exceed 11/4 erythema doses. Where possible the cases were followed for six to eight weeks after the completion of x-ray therapy. This was done in order to observe any recurrence in the original condition presented by the patient. All but one case showed a continuance of the improvement noted at discharge. This case, which had received a total of 3/4 of an erythema dose of x-rays at the time of his discharge returned in two months evidencing a recurrence of itching and scaling between the fourth and fifth toes of The original condition in this patient both feet. had included, besides these recurrent symptoms, vesiculation and heavy scaling of the soles of the feet.

Three cases which illustrate these findings are:

M.H.—Female—White—Age 9.

Diagnosis-Ringworm of feet.

Location—feet.

Duration-four weeks.

Symptoms—itching, vesiculation and sealing on soles of feet.

Microscopic examination positive for trichophyton.

Culture-trichophyton gypseum.

First visit-April 25, 1932.

At this visit the patient was carefully instructed to use nothing but boric acid ointment on her feet. A photograph was taken of both feet. Sone vesicles were opened on both feet and x-rays e.d. $\frac{1}{2}$ unfiltered were applied to the sele of the right foot. The left foot, less involved than the right, was treated with borie acid ointment only.

Second visit-May 2, 1932.

At this time the patient stated that the left foot was quite comfortable for about twenty-four hours with only boric acid ointment. However, during the succeeding days the original irritation returned. The right foot (which had received $\frac{1}{2}$ of an erythema dose of x-rays) was quite comfortable.

Objectively old and new vesicles were to be seen on the left foot, while the right foot showed a few new vesicles with apparent resolution of the old. A photograph was taken and x-rays e.d. 1/4 were applied to the right foot. The patient was instructed to continue using the borie acid ointment.

Third visit-May 10, 1932.

At this visit the left foot showed old and new vesicles and was quite annoying to the patient. The right foot, however, was apparently healed and symptomless. Incision at the sites of the former vesicles on the right foot showed collapse of the vesicles and absence of contents. A photograph was taken of both feet and at the insistence of the patient x-ray therapy was begun on the left foot. Follow-up on this case shows the right foot continuing to be well and the left foot responding to x-rays satisfactorily.

J.G.—Male—White—Age 32.

Diagnosis-Ringworm of hands.

Location—hands.

Duration—six months.

Symptoms—itching, burning, vesiculation, fissuring and scaling patches on palms and dorsum of hands.

Microscopic examination—positive for trichophyton.

Culture-triehophyton rubreum (Castellani).

First visit-April 26, 1932.

Patient instructed to use only boric acid ointment on hands. A photograph was taken of the hands and x-rays e.d. ½ unfiltered were applied to the palmar and dorsal surfaces of the right hand, this being the more involved member. The left hand was treated only with borie acid ointment.

Second visit—May 3, 1932.

At this visit the patient related that the left hand was comfortable with borie acid ointment for about six hours. Subsequently there was a return of the itching and burning which lasted through the remainder of the week. The right hand, however, according to the patient was relieved of its previous symptoms in about thirty-six hours, and continued to be comfortable. Objectively the left hand showed no change from its original condition. The right hand, which had received x-rays e.d. ½ unfiltered showed no vesiculation, less induration, and no fissuring or sealing.

A photograph was taken of both hands and x-rays e.d. ¼ unfiltered were applied to the right hand.

Third visit-May 9, 1932

At this time the left hand showed a continuance of its original condition with no allevation of subjective symptoms while the right hand (after 1 rays 3) of an erythem does had been given) was apparently circular requiring no further ray therapy

After an interval of one more week, when the left hand continued to be unimproved with borie acid ointment treatment with a rays was begin

S McC-Male-Wlute-Age 27

Diagnosis-Ringworm of feet

Location-Toes and plantar surfaces of feet

Duration-four mentlis

Symptoms—itching vesiculation oozing crusting and induration of lesions on dorsiim of feet and sealing be tween foes

Microscopic examination—positive for trichophyton on feet lesions and in toe mails

Culture-trickophyton gypseum

First visit-May 2, 1932

Patient given instructions concerning use of boric acid outlined on both feet. A photograph was taken of both feet. The left foot being the more involved was treated with a rays of $\frac{1}{2}$ infiltered to the dorsum and interdigital spaces of the toes. The right foot was treated only with boric acid outlined.

Second visit-May 9, 1932

At this visit the patient stated that the left foot was very comfortable while the right foot was itching severly, although it had been improved during the first day after borie acid outlinent had been applied. Examination of the feet showed the right foot still cozing and crusting with no evidence of improvement. The left foot showed very marked improvement, there re maintain no cozing resiculation or other signs previously seen except very slight thickening.

A photograph was taken and the left foot given a rays ed 1/4 unfiltered

Third visit-May 16 1932

The left fool to all appearances was cured at this visit. The right foot however showed no improvement

objectively and according to the patient was decidedly uncomfortable

No further a rry therapy was necessary on the left loot, but a rays 1/4 erythema dose was given to the affected areas of the right foot. This case will be followed, as were the others of similar nature.

With regard to the normal medence of ringworm of the hands and feet the records of the Vanderbilt Clinic Mycology Department show that the greatest number of incroscopically and culturally positive eases occur during the spring and stunmer mouths with a subsequent decrease in the number of these eases throughout the fall and winter mouths

In summary the intent of this report has been to determine the usefulness of 1 tays in the treatment of ringworn of the hands and feet petus for this urdertaking was provided by the numerous controversies concerning the actual value of 1-rays in the treatment of this affection The procedure followed was chosen as such, he eanse it seemed to be the fairest and most un biased atlack on the problem. In the interpretation of the results provided by this work it has not been the intention to discuss the superior merits of 1-ray therapy in ringworm over those of a considerable number of other well recognized curative procedures. However, it is felt that the question which promoted this research has been answered and that it may be said that a rays are of value in the treatment of ringworm of the hands and feet

In closing, I wish to express my appreciation to Doctor George Clinton Andrews for his helpful suggestions and guidance throughout this work and also to Miss Mary E Hopper of the Mycology Department of the Vanderbilt Clinic

PSYCHOANALYTIC FACTORS IN FAMILY DISCORD*

By C P OBERNDORF, M D, NEW YORK, N Y

CCORDING to a legal decision a family is formed when two people marry opinion differs from the popular conception that a family comes into being only after the birth of a child The legal construction of the term corresponds with the new psychological attitudes which begin to take form in the two individuals from the moment they have been pronounced man and wife. The situation immediately after wed lock embodies many of the potential elements for happy or discordant family adjustment that moment each member is unconsciously in fluenced by his or her positive or negative attitude toward offspring. The mental attitude toward progeny is not deferred until the birth of the child nor does it await the actual knowledge of conception on the part of the woman. The marriage

* Read at the Annual Meeting of the Medical Society of the State of New York at Buffalo N Y on May 24 1932

ceremony releases many unconscious forces which have lain relatively dormant from early childhood.

The desire to marry, to form a family, begins to take shape and occupy the attention and fantasy of most children from the age of four or five nr even earlier. The interest is revealed in their games and stories Probably every adult sat as a wide eyed child in rapt attention on the floor and listened to the tale of the beautiful princess and And each adult remembers the stalwart knight throughout his life the ending-"They married and lived happily ever after" When the routing story of the prince and the princess began to pull a bit from its nightly repetition and a variation of the old theme replaced it, the child knew it was bed time when he heard the soothing voice saving "and then they grew up and married and lived happily ever after"

We may pause to reflect why the adult always

decidedly more comfortable. When reviewed objectively, the offending members showed little or no improvement in that to which the boric aed ointment had been applied while there was obvious benefit to the member treated with x-rays. The patient was instructed at this visit to persist in the use of the boric acid ointment for another week. At the end of two weeks, after 3/4 of an erythema dose of unfiltered x-rays had been given, the patients were again interviewed. At this time the difference in the condition of the hand or foot exposed to x-ray therapy and that treated only with boric acid ointment was even more accentuated. The untreated member showed no improvement whatever, or negligible amounts of improvement, while the member treated with x-rays was either entirely cured or well on the way to recovery.

It might be added at this point that, where vesicles appeared at the time of presentation on either member, some were opened and others were allowed to remain unopened. This procedure seemed to have made little difference toward recovery, since at the end of two weeks the part treated with boric acid ointment showed numerous recurrent vesicles as well as many new ones. However on the irradiated member, when the sites of the previously unopened vesicles were incised (after x-rays e.d. 34 had been given) the contents of the vesicles had apparently been absorbed and the lesions themselves resolved. Also there were no new vesieles present on this hand or foot.

At the end of three weeks it became necessary to institute x-ray treatment of the previously untreated member because of the discomfort of the patient as well as of his impatience. The results obtained after both hands or feet had been exposed to x-rays not only were satisfactory to the patient but definitely informative to the observer. Because of the apparent beneficial effects of the x-rays in those cases which had not shown a complete clinical cure after 3/4 of an erythema dose, further x-ray therapy was given. The total fraetional dosage of x-rays given to any one case did not exceed 1¹/₄ erythema doses. Where possible the eases were followed for six to eight weeks after the completion of x-ray therapy. This was done in order to observe any recurrence in the original condition presented by the patient. All but one case showed a continuance of the improvement noted at discharge. is a fallacy to suppose that marriage per se will markedly alleviate or cure such a pathological situation

A neurotic man and a neurotic woman may find themselves drifting together through a sympathy based upon an unconscious identification with each other. Marriage must be regarded as the most exacting form of psychosexual relationslip and social adaptation existing today. It entails not only the fulfillment of physical obligations but in addition a necessity for self sacrifice, affection and love which cannot be allowed to lapse for any considerable period of time capacity of the neurotic person to love is restricted -far more than he is consciously aware fact alone suffices to cause disharmony in marriage. A failure in adaptation on the part of either the man or the woman may show itself in any one of a myriad of symptoms ranging from sleeplessness to a severe phobin. However, the likelihood for disorganization in marriage is less if one of the individuals, husband or wife, is normal

The sources of incompatibility among the parents themselves are three firstly, the Cidipus situation, secondly, emotional immaturity, and thirdly unconscious homoseximity

1 The Edipus situation carries with it two stipulations—firstly, the desire to possess for one's self a person in the role which the individual so desired as a child, and secondly, the prohibition of meest. Thus when the individual has obtained through marriage the goal of possessing the hus band or wife, the prohibition against incest may arise unconsciously. This is especially so when the man's unconscious attachment to his mother or the woman's to her father has not been fully At the outset of every marriage the participants normally are handicapped by these two unconscious antagonistic strivings. It seems very likely that the waning of sexual interest after marriage cannot be accounted for entirely by the explanation of repetition and fulfillment of sex gratification but may be partly due to a recur rence of the unconscious prohibition against in The delay in the appearance of aversion to the wife is due to the fact that during the first period of married life the man regards the woman not so much in her wifely role but as a sex love object As this sensious desire is being appeared, the wife in her new surroundings gradually as sumes the mental image and some times even the body-inage of the mother of childhood with the reactivation of the prohibition against sexuality This feeling is apt to occur most signally when the individual's unconscious attachments are exceptionally strong and the mate in marriage is a replica of the forbidden parent Indeed this general formulation can best be demonstrated in decidedly pathological instances, but it is precise ly from the gross cases that we are able to reason the presence of similar mechanisms in subtler

2 Emotional immaturity in parents is closely associated with their own strong parental attach-Parents with a keen counter-attachment to their children artificially foster a dependency of the children and in order to assure this dependency impose unusual prohibitions against freedom. Only when the infantile affective ties to the home and parent have been finally ruptured It is well ean full entotional maturity develop known that emotional maturity does not neces sarily go hand in hand with intellectual develop ment Emotionally immature persons continue to yearn for excessive affection on the part of the parent and therefore are unable to give their fair measure to the mate and children in marriage relationship

3 Unconscious homosexuality, the third factor in discord between man and wife is usually a matter of identification with the parent of the opposite sex rather than of biological constitution In every male there are certain vestiges of femininity and in every female analogous remnants of masculanty When unconscious homosecurity is particularly strong in the female it leads to discord through the attempt on the part of the woman to assume authority in situations and at times which are particularly liumiliating to the male On the other hand, the femininely inclined male is apt consciously to resent domination with repeated outbursts of ineffectual protest Marriages which seem to be relatively happy but where the male is weak and the female strong depend upon a complementary adjustment of the inverted inconscious strivings. These cases are not numerous

While the birth of a child tends to cement a union through the establishment of a sense of mutual responsibility, at the same time it may tend to disrupt it through the fact that some of the love previously given by the parents to each other exclusively is visited upon the child Thus, the parent who is still emotionally immature, that is unconsciously over attached to his own parent is unable to relinquish his own desire for motherly or fatherly indulgence. Such a person is often incompetent to establish a satisfactory affective relation with his mate in a reasonably short time after marriage. He is apt to regard his offspring as a rival So the man who wishes to be mothered excessively by his wife uncon sciously begins to resent the presence of a male child who receives so much attention and especially in the form of infantile coddling which even though a father he still enjoys so fully

Disharmony among parents themselves is immediately and very clearly, though often unconsciously, transmitted to the children. The discord among siblings has its origin largely in rivalry and competition for the affection of the

parents. This is often unconsciously fostered by the parents themselves. Indeed, no two parents feel exactly the same towards any one offspring. No matter how earnestly parents may attempt to maintain a position of impartiality, they find it impossible not only because of their own unconscious predilections and because each new child in the family inevitably necessitates a readjustment of emotional distribution. Thus, no two siblings, even in the most static household, are ever raised in exactly the same emotional or even physical environment because each new child creates a decided and permanent alteration in the environment.

Among the siblings themselves when they are of different sexes, but at times when they are of the same sex, an attempt may be made to duplicate the parents' rôle in the nursery, and even in later social associations. A strong unconscious attachment between two siblings of the same sex may fixate a homosexual tendency which in later life prevents transition to heterosexuality. times the close attachment between brother and sister, for instance, which has all the unconscious emotional implications of marriage may be the unconscious cause of conscious hostility to each other or may lead to attempts later in life to prevent the marriage of one of the parties. brief citation of a case will serve to illustrate the operation of this mechanism in a family situation.

The patient, aged thirty-two, a college graduate, applied for treatment primarily because he could not decide to marry a young woman with whom he believed himself in love. In addition to this urgent social situation he had long been troubled with the fear of jumping from the window, a fear of cutting his finger, a constant irritability and a relative impotency. The patient had had an over strong attachment for his mother, who in turn occupied the dominant figure in the household. Indeed, the father had been relegated to the position of a negligible drudge. The patient at the age of twelve had attempted coitus with a sister aged sixteen, but she repulsed him. She grew into womanhood and while he was away at college became engaged to a man whom the patient had never seen. Upon his return home he immediately took a violent dislike to the sister's betrothed which continued unabated after her marriage. His sister and her husband then moved to another city so that the patient seldom came in contact with them.

About four years after marriage his sister's husband found himself in financial difficulties and the patient immediately began to agitate for a divorce of the couple. By this time he had become the most influential member of the family circle. Not only had he superseded his father but had assumed the rôle of head of the family. His sister seemed disinterested in divorcing her husband, but the patient insisted that his mother

visit the sister in her home and arrange for a divorce because he "could not bear to think of his sister in want." The mother returned from the visit to the daughter apparently unconcerned about the situation. In her opinion the daughter seemed reconciled to her reduced circumstances. When the patient heard that his mother had not carried out his wishes, he flew into a rage, accused his mother of incompetence and lack of interest in her daughter's welfare. On the very same day he took a train to the place where his sister lived and finally maneuvered to induce his sister to sue for divorce. She returned to live with the family where she passed under his control. He then permitted her to become a clerk in a department store although he could well have supported her.

The patient remarked, after five months of analysis, "Now I realize why I engineered my sister's divorce—I really insisted upon it—but when I did it I was entirely unconscious of my motives." The unconscious motive which prompted the patient to interfere was his own desire to possess the sister and this in turn made it intolerable for him to see her attached to any one else. The patient eventually began to realize that no matter to whom his sister might have been married his attitude to the husband would have been the same as it was to his inoffensive and incompetent brother-in-law.

The extent of the patient's attachment to his sister was revealed in frankly incestuous dreams concerning her after six months of analysis and three months after his own marriage. The patient's marriage during the analysis was contrary to the well-established rule that a patient should undertake no very decisive and relatively irrevocable decision during the time that he is under analysis. In this case the patient attempted to bind himself by the formality of marriage because he feared that without a precipitate and drastic step he might never be able to undertake it.

The value of the physician's experience in familial controversy has been recognized for many centuries, but his advice hitherto has been pri-The establishment of child marily intuitive. guidance clinics in many cities of this country and of matrimonial consultation bureaus under medical direction in some of the German cities has brought the scientific contributions of mental medicine into closer touch with the allied fields of pedagogy and social hygiene. The tendency of judges in domestic relations courts and of lawyers, who are often the first to be consulted in cases of marital discord, to refer the dissatisfied parties to psychiatrists for opinions and treatment indicates that the scientific application of psychiatric and psychoanalytic discoveries is on the increase in these difficulties.

Indeed, psychoanalysis has deepened our knowledge of the sexual and allied difficulties which exist in every marrige. The better we understand them the greater will be our capacity to alleviate the intricate situations which arise. The revelations of psychoanalysis may and already are calling for alterations in our social scheme. If science points the way to new regnlations in regard to certain institutions which have been regarded as permanent, or even sacred, it is merely following the inevitable changes in other social

views which have resulted from scientific discoveries—for instance, the prohibition against the custom of draining sewage into streams when it was proven that such practices led to pollution and typhoid. If our more enlightened grasp of underlying factors in family discord leads to greater latitude in divorce regulations, if it tends to shake the stability of the home or eventually lends its force to a recasting of marital obligations, morals and ethics, these possible sequences are not the primary concern of the scientific investigator.

CHRONIC DUODENAL OBSTRUCTION By ROSS GOLDEN, M.D., NEW YORK, N. Y.

From the Roentgen Ray Department of the Presbyterian Hospital and the Department of Medicine of the College of Physicians and Surgeous, Columbia University, New York, Read at the Annual Stetting of the Medical Society of the State of New York, at Bullalo, N. Y., May 24, 1932.

Tile roentgen ray examination of the gastrointestinal tract is usually undertaken for the purpose of determining the presence or absence of peptic uleer or malignancy. The absence of these pathological processes does not necessatily mean that the examination is without significance. It should be, in addition to a search for these important diseases, an anatomic and physiologic study through which may be revealed information of great value in explaining the patient's symptoms.

Among the less frequently encountered causes of digestive disturbance is the condition which may be termed chronic duodenal obstruction. The fact of its existence has been known for years; yet it seems to be all too frequently ignored, probably because its manifestations are often vague and indefinite. The recognition of it depends primarily upon the roentgenologist. Unless he appreciates the significance of abnormalities of physiology as well as of filling defects and crater shadows, it will not be detected.

Chronic duodenal obstruction is frequently associated with or arises from developmental variations in the duodenum and its attachments. It is not possible here to discuss the embryologic origin of these anomalies (see Dott). For clinical purposes they may be classified roughly under three general headings (Fig. 1). 1. Variations in the bepato-duodenal ligament. 2. Anomalies in the position of the duodeno-jejimal junction and in the peritoneal reflections about it. 3. Accessory peritoneal bands or membranes springing from the under surface of the liver and around the root of the gall bladder. Any one of these conditions may appear alone or in combination with the others.

Chronic duodenal obstruction may be eaused by pressure of the superior mesenterie or dextrocolic artery on the ascending limb of the duodenum and occurs most frequently when the duodeno-jejunal junction overlies the spine.

Recent observations on the physiology of the

duodenum are of great interest in this connection. Dragstedt and Dragstedt showed that extrinsic circular pressure by a rubber hand sufficient to resist the pressure of only six inches of water is enough to cause duodenal obstruction and death in a dog. Much greater pressure is necessary to produce the same effect in lower portions of the intestine. Ivy found that distending a rubber balloon in his own duodenum produced a characteristic type of nausea and, less frequently, pain.

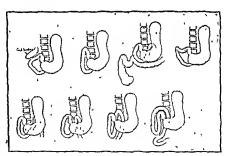

FIGURE 1

A diagrom of vorious types of developmental anomalies of the duadenum as seen on roenlyen ray examination. The upper row shows variotions in the hefoto-duadenal ligament. The lower row shows the various stages in the shift to the right of the duadeno-jejunal junction. The lower left sketch represents the average normal position; the lower right is the extreme degree of displacement where the third portion rises to the right of the second and the duadeno-jejunal junction overlies the right side of the vertebrol column.

SYMPTOMS

The most common symptoms are vague distress after eating, a full feeling after only a little food is eaten, nausea, voniting with relief and less frequently attacks of pain. Alkalies give

only moderate and temporary relief, if any. The symptoms are not relieved by eating as in ulcer. They are aggravated by coarse foods. The patients sometimes state that they would be comfortable if they could get along without eating. This leads to undernutrition and physical inefficiency. They frequently tell of having gone from doctor to doctor and of being told that nothing is the matter with them. They often present the picture of neurasthenia and maladjustment.

It is often difficult, particularly in border-line cases, to determine the importance of the emotional, functional or psychic elements in explaining the symptoms. That this aspect of the problem is of great importance and sometimes predominates was emphasized by Dr. Allen O. Whipple, speaking from the standpoint of a surgeon, in a recent lecture before the Chicago Institute of Medicine. Dr. Robert B. McGraw, our consulting psychiatrist, who has studied carefully a number of these patients, states that the emotional reactions are too variable to be classified in an orderly manner. He agrees that the physiological aspect is of prime importance but points out that anxiety neuroses and environmental maladjustments must nevertheless receive suitable attention.

The symptoms associated with this condition occasionally manifest themselves in infancy or childhood but may not appear until later life, even in middle age. If their source lies in a condition which has been present all the patient's life, why is their appearance delayed? It is frequently noted that the onset occurs after something which lowers the patient's vitality, e.g., an attack of influenza or a period of unusual strain. Dr Alfred Taylor's conception of the compensation of a viscus for an anatomical handicap and of decompensation under strain, analogous to what takes place in a diseased heart seems particularly happy. As long as the stomach and duodenal bulb, for example, can successfully overcome a hindrance at the junction of the first and second portions of the duodenum no symptoms are present. When, however, intercurrent disease, the increasing strain of life, or even some temporary indiscretion in diet intervenes, the balance is upset, proper emptying does not take place and symptoms develop.

DIAGNOSIS

The diagnosis depends primarily upon the roentgen ray examination. The importance of a careful fluoroscopy cannot be overemphasized. Aside from the developmental anomalies mentioned previously, it may disclose varying degrees of delay in and dilatation of one or more portions of the duodenum, a six-hour residue in the duodenum and even in the stomach, and sometimes the gastric dilatation, atonicity and abnormal peristalsis which go with chronic obstruction. Extraneous bands may cause deformities of the bulb

very difficult to differentiate from those of ulcer. Active reversed peristalsis in the second portion is frequently encountered. It is sometimes possible to see a thinned area where the duodenum crosses the spine or at the duodeno-jejunal junction when a bolus of barium is squirted through, suggesting pressure from without. The effect on the emptying of the second portion by changing from the upright to the prone position and of manual pressure on the lower part of the abdomen should be observed. It is usually not difficult to determine whether the second portion of the duodenum is intraperitoneal or is fixed behind the peritoneum as it should be.

The summing up of the evidence in such cases requires the correlation of the anatomic and physiologic data assembled from careful roentgen ray studies with the clinical picture.

TREATMENT

A brief statement of the measures ordinarily used in the treatment of this condition would include frequent small feedings of low residue, high-calory food, exercises intended to strengthen the abdominal musculature, a belt appliance to lift up the lower abdomen and gastric lavage with great care not to overdistend the stomach. In undernourished individuals an increase in weight is often associated with relief of symptoms. Adequate rest must be taken and undue fatigue and strain avoided. If symptoms persist in spite of these measures or if the maintenance of compen-

FIGURE 2. CASE 1

The stomach of a boby seven days old who had vomited all feedings since birth. This was watched with the fluoroscope at intervols for four hours during which time very little barium possed beyond the duodenal bulb. The obstruction of the junction of the first and second portions was thought to be rother more suggestive of a duodenal band thon of a developmental atresia.

sation so limits the patient's activities that life becomes difficult, the question of surgical intervention arises. The surgical procedure is usually intended to relieve the mechanical difficulty or to short-circuit it (Taylor; Duval, Roux and Beclere).

CASES

The following cases are shown as examples of the importance of recognizing this condition.

Case 1. A bahy seven days old was sent to the roentgen ray department by the obstetrician. Dr. Chas, E. Caverly, because he had vonited all of his feedings since birth. Fluoroscopic observation at intervals over a period of four hours showed that very little if any barium left the stomach. The obstruction seemed to be at the function of the first and second portions of the duodenum (Fig. 2). Congenital atresia and a duodenal band were suggested as possible causes. The latter seemed more likely because the obstruction was at the first and second portions. The bahy was operated upon by Dr. R. F. Carter, A duodenal hand (Fig. 3) was found and severed.

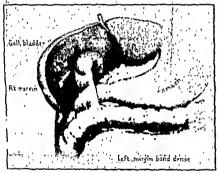

FIGURE 3. CASE 1

A drawing based on a sketch made by the surgeon. It shows semi-diagrammatically the band found at operation, on the week-old baby; a roentgenogram of whose stomach is shown in Fig. 2. The band seemed to be responsible for the obstruction at the function at the first and second portions of the dualenam.

A tube was passed through the esophagus, stomach and duodenum into the jejimum (Fig. 4) showing that no atresia was present. After operation the baby took his feedings in a normal manner and has thrived.

Case 2. A forty-two-year-old nurse had never been able to take more than the shiplest nuels without immediate gastric distress, frequently associated with nausea and vomiting. For years she subsisted on pureed food but had symptoms in spite of it. If she abstained from food the distress was relieved. During the year and a half previous to admission the symptoms became worse. She lost thirty-five pounds in eight months. For one month she vomitted every meal and the vomitus frequently contained bright red blood. There was apparently a large psychic element in the case, in which an unfortunate love

affair played a major role. During a period of years she had been seen by a number of doctors

FIGURE 4, CASE 1

effer the operation at which the duodenal band shown in Fig. 3 was severed, a tube was passed through the aesophagus, stomach, and duodenum into the jejunum, showing that no congenial arcsia existed and that the obstruction was fuc to the band. Since operation the baby has thrived, I am indebted to Dr. R. F. Carter for the film reproduced here.

and had been told there was nothing the matter with her. A barium meal disclosed, in brief, an

FIGURE 5. CASE 2

A film of the gastrointestinal tract of a 42-year-old nurse who had suffered from gastric symptoms for years. The duodenal bulb is enormously dilated, indicating obstruction at the junction of the first and second portions of the duodenum. At antopsy a band, analogous to that found in the body (case 1), was found running from the under surface of the liver across the upper part of the descending limb of the duodenum. Cystic gastritis was present in the autrum of the stomoch.

enormous dilatation of and a five-hour residue in the first portion of the duodenum and a very small gastric residue (Fig. 5). After admission, in spite of frequent small feedings of soft food, she continued to vomit and two weeks later developed gastric tetany. A jejunostomy was done, hoping to get her in condition for a more extensive surgical procedure. She lost all desire to She continued to vomit, developed a gangrenous cellulitis of the left thigh and died on the eighty-eighth day after admission. Autopsy disclosed a thick peritoneal band extending from the under surface of the right lobe of the liver to the upper part of the descending limb of the duodenum, five cm. in width and eleven cm. long. Cystic gastritis was found in the prepyloric region of the storach (Fig. 6).

FIGURE 6. CASE 2

Cystic yastitis associated with chronic duodenal obstinction due to a duodenal hand; a photomicrograph from a section taken from the autrum of the stomach

Case 3. A fourteen-year-old girl was sent to Dr. Robert B. McGraw as an emotional feeding problem. About four months previously she lost her appetite and began to lose weight. was some evidence that this was initiated by dieting to get thin. She was twenty pounds under weight. She resented all efforts to make her eat because she felt stuffed and at times nauseated A roentgen examination of the gastro-intestinal tract (Fig. 7) disclosed a small six-hour barium residue with considerable fluid in the stomach. The second portion of the duodenum contained a good-sized six-hour barium residue, was freely movable, dilated, showed marked delay in the passage of barium with active reversed peristalsis and regurgitation into the stomach (Fig. 8). The third portion of the duodenum rose over the spine and was seen to move rhythmically and synchronously with the pulse as if it were in contact with the aorta or the superior mesenteric artery. The delay in the duodenum seemed to be due to an obstruction at the duodeno-jejunal junction. Attempts at treatment for a time were futile. She was sent to a sanatorium where she was tube-fed for over a week during which she gained seven pounds. Then her appetite suddenly returned, she began to eat and gained thirty pounds in two months.

Case 4. A man of thirty-eight came to the hospital in 1924 complaining of gastric symptoms

FIGURE 7. CASE 3

el siv-hour residne in the stomach, bulb and second portion of the duodenum in a 14-year-old girl. The patient was 20 lbs, nuder weight. She was referred for evanination of the stomach by the psychiatrist to whom she was sent as an emotional feeding problem.

of five years' duration. At the onset he had the sensation of a lump in his stomach, relieved by avoiding certain coarse foods such as cabbage. For three months he had nausea and voniting

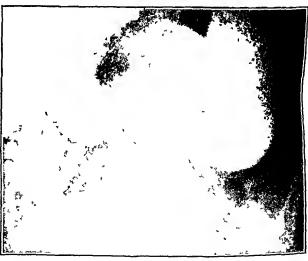

FIGURE 8. CASE 3

Chronic obstruction at the duodeno-jejunal innetion (same case as in Fig. 7). The second portion of the duodenum is dilated. The third portion of the duodenum ises over the right side of the spine and its upper part was seen fluoroscopically to move rhythmically with the pulse indicating intimate contact with the aorta or some large artery. The second portion slauts to the right, suggesting an extension of the hepato-duodenal ligament ont over the gall-bladder and over the anterolateral margin of this part of the duodenum.

three to four hours after meals almost daily and for one week severe epigastric pain, worse at night and relieved by vomiting. He was markedly undernounished. A roentgen examination of the gastro-intestinal tract (Figs. 9 and 10) dis-

Figure 9. Case 4

An enormously dilated stomach with puddles of barium in the first and second portions of the duodenum. The fatient was a man of 35 years of age who had symptoms of several years duration suggesting a duodenal ulcer. (See Fig. 10.)

closed a dilated hypotonic stomach with a large six-hour barium residue and much fluid, duodenal bulb was very long and seemed to be angulated at its junction with the second portion where there seemed to be a hindrance to the passage of barium. Three examinations failed to disclose evidence of peptic ulcer. Small feedings of low-residue food gave relief only as long as the patient remained in bed. After two months of dietary treatment he was operated upon by Dr. D. C. Bull. Although the lower end of the stomach and the duodenal bulb were opened and examined from within, no evidence of peptic ulcer could be found. There was a band between the inferior surface of the gall-bladder and the anterior surface of the duodenium running back to the angle between the cystic duct and the duodenum. It was about eight em wide. surgeon's impression was that this band was causing obstruction. He severed it, removing the gall-bladder to peritonealize the cut surface. The position of the junction of the first and second portions of the duodenum was lowered. After an uneventful convalescence the patient's symptoms disappeared. When seen by Dr. Bull in 1930, six years after operation, he was having no trouble except after eating calbage or indulging too freely in soda water. In the spring of 1931 I requested him to return for another roentgen examination and found that he had been having indigestion for the preceding few weeks.

FIGURE 10. CASE 4

The stomach shown in Fig 9 in the right prone position. The duodenal bulb is very long. The junction of the bulb with the second portion is sharply angulated A operation the upper part of the second partion was unted to the goll-bladder by a dense band which seemed to be causing obstruction. The removal of the band was followed by freedom from symptoms for over six years when the patient developed a gastric ulcer.

The examination disclosed a peptic ulcer of the lesser curvature of the stomach. The duodenal bulb was still long but its contour was different and there was no evidence of delay in the passage of barium through it.

SUMMARY

Cases 1 and 2, presented above, show duodenal obstruction from essentially the same type of band in a new born iofant and in a woman in the fifth decade of life. In the latter it was associated with definite pathologic changes in the stomach wall (cystic gastritis) which are undoubtedly the result of a chronic inflammatory process, probably based on long continued gastric stasis. In the former it was immediately relieved by the severing of the obstructing band. Case 3 was a chronic duodenal obstruction located at the mis-

enormous dilatation of and a five-hour residue in the first portion of the duodenum and a very small gastric residue (Fig. 5). After admission, in spite of frequent small feedings of soft food, she continued to vomit and two weeks later developed gastric tetany. A jejunostomy was done, hoping to get her in condition for a more extensive surgical procedure. She lost all desire to She continued to vomit, developed a gangrenous cellulitis of the left thigh and died on the eighty-eighth day after admission. Autopsy disclosed a thick peritoneal band extending from the under surface of the right lobe of the liver to the upper part of the descending limb of the duodenum, five cm. in width and eleven cm. long. Cystic gastritis was found in the prepyloric region of the stomach (Fig. 6).

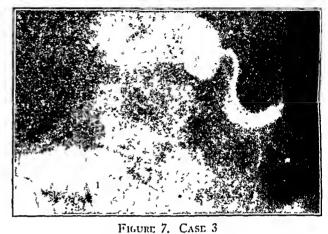

FIGURE 6. CASE 2 Cystic gastritis associated with chronic duodenal obstruction due to a duodenal band; a photomicrograph from a section taken from the antrum of the stomach.

Case 3. A fourteen-year-old girl was sent to Dr. Robert B. McGraw as an emotional feeding problem. About four months previously she lost her appetite and began to lose weight. was some evidence that this was initiated by dieting to get thin. She was twenty pounds under weight. She resented all efforts to make her eat because she felt stuffed and at times nauseated. A roentgen examination of the gastro-intestinal tract (Fig. 7) disclosed a small six-hour barium residue with considerable fluid in the stomach. The second portion of the duodenum contained a good-sized six-hour barium residue, was freely movable, dilated, showed marked delay in the passage of barium with active reversed peristalsis and regurgitation into the stomach (Fig. 8). The third portion of the duodenum rose over the spine and was seen to move rhythmically and synchronously with the pulse as if it were in contact with the aorta or the superior mesenteric artery. The delay in the duodenum seemed to be due to an obstruction at the duodeno-jejunal junc-

tion. Attempts at treatment for a time were futile. She was sent to a sanatorium where she was tube-fed for over a week during which she gained seven pounds. Then her appetite suddenly returned, she began to eat and gained thirty pounds in two months.

Case 4. A man of thirty-eight came to the hospital in 1924 complaining of gastric symptoms

A six-hour residue in the stomach, bulb and second portion of the duodenum in a 14-year-old girl. The patient was 20 lbs, under weight. She was referred for exami-

nation of the stomach by the psychiatrist to whom she was sent as an emotional feeding problem.

of five years' duration. At the onset he had the sensation of a lump in his stomach, relieved by avoiding certain coarse foods such as cabbage. For three months he had nausea and vomiting

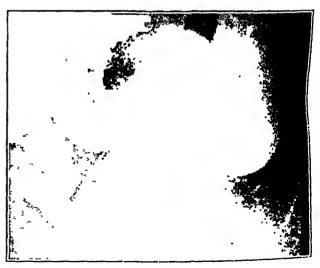

FIGURE 8. CASE 3

Chronic obstruction at the duodeno-jejnual junction (same ease as in Fig. 7). The second portion of the duodenum is dilated. The third portion of the duodenum rises over the right side of the spine and its upper part was seen shoroscopically to move rhythmically with the bulse indicating intimate contest with the gorge or some pulse indicating intimate contact with the aorta or some large artery. The second portion slants to the right, snggesting an extension of the hepato-duodenal ligament out over the gall-bladder and over the anterolateral margin of this part of the duodennin.

Figure 1.
Parasaggital meningcoma. Localized increased vascularity.

the sites of election of the meningeomas, it is fairly certain that this is the type of tumor we are dealing with, which proved to be the case in the skull shown in Figure 2.

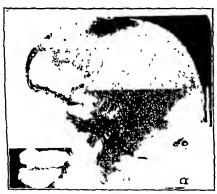

Figure 2.

Calcification in a Parasaggital meningcoma

In Figure 3 we have a skull harboring a meningeoma arising along the olfactory groove of the ethmoid. This is a fairly common site for these tumors. They occasionally calcify, as can be seen in the illustration, and also frequently produce some bony overgrowth of the floor of the anterior fossa. They not infrequently are found to be of the rather flat, spreading, so-called "en plaque" type, and they often extend back as far as the sphenoid ridge. Tumors in this location, as might be expected, produce as their earhest

symptoms, anosmia and vague personality changes, so often associated with frontal lobe lesions.

In Figure 4 we have a meningeoma of the sphenoid ridge. In the illustration this may appear very similar to the case seen in the previous illustration, but instead of calcification in the

Figure 3
Meningcoma arising along the olfactary groave,

tumor this case shows bony production which usually can be differentiated by careful examination of stereoscopic films including postero-anterior views. These tumors not infrequently invade the orbit and produce unilateral evolutialmos. In Figure 5 we have the same case showing the thickening over the orbit and along the sphenoid ridge.

Figure 4
Meningcoma extending over sphenoid ridge

Figure 5.

Same as Figure 4 Note bone thickening of sidge and over orbit.

In Figures 6 and 7 we have illustrations of these tumors invading the orbit and producing unilateral exophthalmos. In Figure 6 the posterior wall of the orbit can be seen to be partially destroyed, as in this case the osteolytic tendencies predominate, but in Figure 7 the osteophytic tendencies have the upper hand and the orbit is seen to be almost filled with an over-growth of bone.

In Figures 8 and 9 we have a case in which the meningeoma originated in the wall of the lateral sinus and spread upward to involve the petrous pyramid, producing a large amount of dense, bony over-growth. In Figure 8 fine lines of calcification can be seen which roughly outline the extent of the tumor itself. In spite of the size of this tumor, it is interesting to note that the sella is practically intact.

FIGURE 6
Meningcoma which has destroyed posterior orbital wall.

Figure 10 is of a skull which shows several poins of interest. In the first place, the 1ay-like sunburst effect in the frontal bone is quite characteristic of the meningeoma which has both osteolytic and osteophytic tendencies, but in this

Figure 7.

Meningeoma invading orbit and producing hyperostosis

case a shadow of calcification is seen just back of the sella which I rather think may well be the site of another tumor, although, unfortunately, this was never definitely proved. It is also to be noted

FIGURE 8

Meningcoma near lateral sinus. Note dense bone production and calcification in tumor

that the sella shows considerable destruction. The dorsum is almost completely absorbed.

In Figure 11 we have a case in which a large

meningeoma was found in the parieto-occipital region. Here again, osteolytic and osteophytic tendencies are to be seen. There is also marked increase in vascularity.

Figure 12 shows still another manifestation of

Figure 9. Same as Figure 8.

these tumors, in which we have considerable hyperostosis along the sphenoid ridge, and another area of hyperostosis under the bregma but, strange to relate, this area under the bregma, when removed, seemed to be perfectly normal bone.

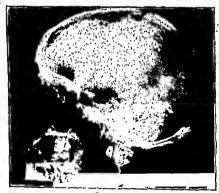

Figure 10,

Meningeoma of frontal region. Note "sun burst" effect
in the bone,

The last case that I am showing is illustrated in Figures 13 and 14. This is of a rather large parasaggital meningeoma which, beside showing

Figure 11.

Large meningcoma in parieto-occipital region.

calcification, has also invaded both tables of the skull and emerged under the scalp, producing a lump, which was the only thing worrying the patient. The soft tissue film shown in Figure 14 clearly demonstrates the spiculations on the outer table, produced by these tumors, not unlike spiculations often seen with the osteogenic sarcomas in other parts of the skeleton. It is not uncommon for these comparatively benign looking lumps under the scalp to be diagnosed as sebaceous eysts or other simple lesions, because the intracranial symptoms are frequently so vague and obscure that they do not impress either the patient or the physician.

In summary, then, let me call attention to the

FIGURE 12.

Large meningeoma with hyperostosis of sphenoid ridge
and under bregma.

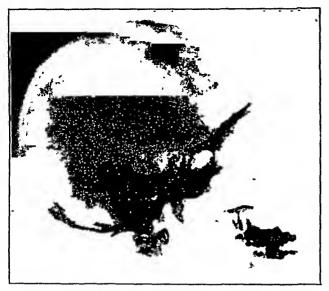

FIGURE 13. Parasaggital tumor with calcification and extension through skull.

manifold changes these lesions can produce, but they nearly all will be seen to have some tendencies toward bone production if only by the formation of small spicules. Increased vascularity is another characteristic which, when seen unilaterally, may be of considerable significance, but it must be borne in mind that unilateral increased vascularity can also be caused by the haemangeomata. These, however, are comparatively rare, and very frequently by the use of the stethoscope a bruit can be heard which makes the differentiation from the meningeomas comparatively easy.

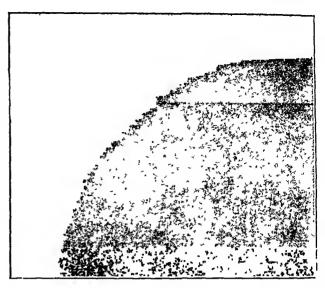

FIGURE 14. Same as Figure 13. Soft tissue film showing spiculation on outer table.

When we see a shadow indicating bony overgrowth in the sites of election of these tumors, and when the patient complains of a long, rather vague clinical history, we are usually justified in making a positive diagnosis of a meningeoma.

In closing, let me emphasize the importance of obtaining stereoscopic films with the aid of a Bucky diaphragm, and also it is equally important not to attempt to interpret skull films without being thoroughly acquainted with the clinical findings, for all meningeomas do not manifest themselves as unmistakably as those I have selected for the illustrations.

THE AMERICAN MEDICAL ASSOCIATION

The New York State Delegates have given glowing accounts of the Annual Meeting of the American Medical Association which was held June 12-16 in Milwaukee, Wisconsin The absence of lengthy discussions on the floor of the House of Delegates was reflected in a meagerness of the news of the meeting carried by the daily papers, but in fact more discussions than usual

took place before the committees, many of which held lengthy hearings at which an opportunity to speak was given to scores of physicians besides those who were duly accredited delegates

New York State was honored by the unanimous election of Dr Nathan B Van Etten of Bronx County, as Vice Speaker of the House of Delegates

INSURANCE FOR HOSPITAL SERVICE

A confusion is sometimes made between the consideration of a question and a decision regarding it.

A patient often asks his physician to give an opinion regarding an advertised method of treatment. If the patient is merely curious, he will be satisfied with the casual opinion of the doctor; but if the patient is anxious to try the advertised treatment, the doctor will be compelled to give serious consideration to the method, to ascertain the facts regarding it, and to take positive steps to influence the patient either for or against it.

Likewise a medical society is often compelled to consider an activity which is widely advertised by methods of propaganda. When medical societies refuse to discuss the medical problems which are common subjects of newspaper articles and radio talks, or when they discuss them only in ridicule, the medical profession suffers in its reputation for broadminded judgment. Medical leaders in these modern days realize the desirability of giving serious attention to the new problems which are constantly arising, especially those regarding medical economics and medical administration.

When a new subject is under consideration, the usual course which is taken by medical societies is to appoint a committee to ascertain the facts, and to advise the members as to the attitude that they should take,—either rejection, or further study, or approval, or active support of the plan. The fact of appointing a committee of investigation is not to be interpreted as support of a proposed activity. It may simply mean that the members do not know enough about a subject to form an intelligent opinion regarding it; but that they have an open mind and are willing to learn the basic facts about it.

The significance of the appointment of a medical society committee on a new subject may be interpreted in diametrically opposite ways. The propagandist may claim that the society has taken the first steps toward adopting his plan,—when it might equally well be interpreted as its rejection. On the other hand, those of the reactionary group may claim that the disclosure of the facts will forever dispose of the further consideration of the new plans.

A specific illustration of the different interpretations of the attitude taken by a medical society is contained in an article in the *New York Times* of Sunday, June 18, 1933, on the subject "Sickness Insurance Gaining New Ground," in which the author, an employee of one of the large "Funds." says:

"In New York the State Medical Society, at its annual meeting in April, adopted a committee report which endorsed two of the plans which had been recommended by the committee on the Costs of Medical Care: first, more adequate medical care of the unemployed and indigent and payment to physicians for such service; and, second, group hospitalization,—paying for hospital care by an annual fee."

The two plans which are mentioned in the quotation were discussed in the report of the Special Committee appointed to consider the report of the National Committee on the Costs of Medical Care. This Special Committee made its report to the House of Delegates on April 3, 1933, and the report with its recommendations was unanimously adopted. (See this Journal May 1, 1933, page 594).

Regarding the worthy poor and the indigent, the Special Committee approved a system of relief which has been required by a Statute Law of the State of New York for over three years, and which has operated satisfactorily wherever the medical profession and the public officials have worked in cooperation.

In contrast with the demonstrated efficiency and desirableness of the New York State system of medical relief of the worthy poor, the insurance of hospital service is in its formative stage only, and has not been put in force except in a very few small groups operating under exceptional conditions. What the Special Committee recommended was "The adoption generally of a plan of hospital insurance whose principles may be stated as follows." The report then goes on to enumerate the five principles under which the insurance of hospitalization is recommended, the last one reading:

"In each community, under the supervision of its organized medical group, there shall be developed the details of this plan so as to meet local conditions and make it workable."

It has been the policy of the Medical Society of the State of New York to follow the laboratory method of extending the scope of its activities under the initiative of county societies in which conditions are favorable to the experiment. So far no county society of New York State has formulated a plan for hospitalization insurance, much less started to put one into effect. It is possible, and even probable, that the need of an assured income for some hospital will impel its medical staff to devise an insurance scheme which will be a pioneer demonstration for the encouragement or warning of others.

Ŵ

MEDICAL PROGRESS

Angina Pectoris Diaphragmatica .- It has long been recognized, says L. Hofbauer, that three entirely different causes may form the starting point for an attack of angina pectoris: (1) overdistention of the stomach or intestine, (2) the effect of cold, and (3) exertion or movement. The common factor in these three causes is their influence upon the respiratory movement, upon the statics and kinetics of the diaphragm. For a number of years Hofbauer has uniformly observed in angina pectoris, as an "accessory finding," changes in the position and movability of the di-Especially impressive is the typical connection between operatively treated empyema pleurze and states of angina. Here the causes at work can be demonstrated on both sides, and it is possible to explain the connection between the changes produced in the diaphragm and the resultant angina. Again and again it is the change in position of a patient which in such cases gives rise to the attack, and in one and the same case it is always one definite change-right or left decubitus, a forward or a backward inovement, etc. The patient who has felt perfectly well up to the moment of change of position suddenly becomes deathly pale, is unable to draw a breath, feels an indescribable oppression in the chest, and a sensation of pain which compels him immediately to resume his former position. In all these cases the x-ray reveals a quite definite change in the position of the diaphragm, as well as an obstacle to the movability of this organ. The same impediment to breathing is observed when the diaphragm is pushed far upward by increased abdominal pressure, and also in purely functional hindrance to the activity of the diaphragm. Hofbaner cites two cases to show that even in diapliragmatic liernia the angina disturbances are not in every case caused by secondary changes in the coronary arteries. That an attack of angina pectoris may be caused by a disturbance of the diaphragm is at once understandable in cases where there are cicatricial adhesions of that organ; but in cases where no such mechanical cause is present, pain and obstruction to breathing may arise as the result of a "viscerosensory reflex" in Mackenzie's sense, since the heart and diaphragm correspond to the same segment of the spinal cord. Where there are no organic changes in the diaphragm, a hyperesthesia of that structure may result from changes in the central circulatory apparatus (coronary arteries, aorta, myocardium) by way of this reflex, producing a sense of oppression, inability to draw a long breath, and a painful contraction in the chest-in other words, angina pectoris .- Münchener medisinische Wochenschrift, March 17, 1933.

Insulin and Glucose in the Treatment of Heart Disease.-K. Shirley Smith, writing in the British Medical Journal, April 22, 1933, i, 3772, discusses the insulin and glucose treatment of heart disease with special reference to angina pectoris. After reviewing the literature on this method of therapy in cardiovascular disease, he says that more and more evidence is accumulating to show that auginal pain in general arises not in the aorta, but in the heart muscle, and is attributable essentially to deficiency of coronary blood or blood flow rather than to alterations in blood pressure. Insulin and glucose were given in angina pectoris in the belief that a defect of carbohydrate combustion in the heart muscle is at the root of anginal pain. In an earlier communication Smith drew attention to a group of conditions in which diffuse parenchymatous myocardial damage exists independently of any disease of the coronary system. Examples of these states are general malnutrition or starvation, hypoglycemia, myxedema, and severe di-The evidence that perversion of myocardial function accompanies these disorders of malnutrition is a characteristic deformity of the electrocardiogram, which shows a depression of the RT interval or inversion of the T wave in one or two or all leads. In all of the above-mentioned disorders the electrocardiographic abnormality disappears when the metabolic fault is rectified. The use of insulin and glucose in heart disease is based upon the belief that the promotion of glycogenic utilization in the heart may prevent the accumulation of substances producing anginal pain. But there is evidence that insulin has a further effect upon functional efficiency and nutrition of the coronary arteries. It is well known that accumulations of fat in the deeper layers of the intima constitute one of the earliest stages of atheroma. Dieting experiments have shown that these deposits of fat are removable. It is suggested that the removal of such fat is part of the action of insulin in angina pectoris. The work of Himwich and Spiers supplies evidence in support of this view. During the Past year Smith has studied some forty patients suffering from angina pectoris from the standpoint of treatment by insulin and glucose. He cites six of these case reports in detail, in all of which there was marked improvement under this method. The treatment consisted in giving 5 units of insulin before breakfast and before the evening meal, each dose being followed by 30 grams of glucose taken with the meal. The period during which this treatment was administered ranged from two to seventeen weeks. It is suggested that this method deserves careful and extended trial.

Experimental and Biologic Researches in Diabetes Insipidus (Grafting of Calf Hypophysis in a Patient).—Sacorrafos describes in the Bulletin de l'Académie de Médecine of March 28, 1933, the remarkable results that followed implantation of the hypophysis of a calf in a young man suffering with such an exaggerated case of diabetes insipidus that he had made attempts upon his own life in an effort to rid himself of his misery. Treatment with ordinary extract of hypophysis had brought only fleeting relief, the injections having to be repeated 2 or 3 times in the course of 24 hours to control the intolerable Under the influence polyuria and polydipsia. of this treatment the quantity of urine (14,000 to 16,000 gm. in 24 hours) diminished but never fell to normal, hovering between 2,500 and 3,000. As is known, the mechanism of the treatment is based on the regulating function exerted upon dinresis by the posterior lobe of the hypo-With a view to accomplishing a more lasting result, Sacorrafos implanted the hypophysis of a calf into the sheath of the right rectus The quantity of urine fell at once abdominis. in the first 24 hours to 300 gm., or 1/4 the normal amount. At the same time a repugnance toward water appeared, it being difficult to persuade the patient to drink 400 to 600 gm. per day. This condition lasted two weeks, after which the disease began to return, but never to anything like its former degree during an observation period of approximately three months. It was observed that the lowering of the water threshold and the consequent renewed polyuria preceded by 48 hours the reappearance of polydipsia. The determination of the acid-base equilibrium prior to the grafting showed a shift toward acidosis, revealed in two distinct ways: (1) in the blood. by a diminution of the alkali reserve, and (2) in the renal tract, by chloride retention. After the grafting operation, this equilibrium was re-established almost immediately, tests being made in the morning with the patient fasting. Another interesting observation was the increased difference between maximal and minimal blood pressure after the implantation, a maximal pressure of 9 cm. (Vaquez) and a minimal of 7 cm. becoming respectively 12 cm. and 6 cm. for several days. The calf hypophysis used weighed 850 mg., and thus contained 121 international units of posterior lobe of hypophysis. If 5 injections are made in 24 hours of products which contain 1.4 c.c. per ampule, about 20 units are introduced in 24 hours, so that in 20 days 400 units would have been required, by the standard treatment, to maintain the water equilibrium in the organism. If we take into account the fact that to obtain 121 units nearly 4 calf hypophyses are necessary, the result from implantation of 1 single hypophysis can hardly fail to be surprising. Sacorrafos thinks this observation points the way

to the future treatment of diabetes insipidus by fresh gland.

A New Therapy of Peptic Ulcer: Continuous Alkalinized Milk Drip into the Stomach. -Asher Winkelstein discusses the rôle of the acid factor in the pathogenesis and therapy of peptic ulcer and stresses its importance. He says he has not encountered a single instance of peptic ulcer, proved at operation, without free hydrochloric acid in the gastric contents. He has also been impressed by the rôle of the nervous system (vagus nerve) in the hypochlorhydria of ulcer patients. Furthermore, as demonstrated by the charts here presented, patients with peptic ulcer have a high nocturnal curve of acidity. Because of this observation it may be questioned whether any method of ulcer therapy thus far advocated accomplishes what seems the logical and desirable state, namely, the institution of chronic achlorhydria. For these and other reasons, the following plan of treatment was formulated. A Relifuss tube is passed into the stomach of the patient and connected by a fairly long piece of rubber tubing to a gravity flask, and a Murphy drip indicator is interposed in the system. A solution consisting of milk containing 5 grams of sodium bicarbonate to the quart is allowed to drip into the stomach at the rate of 30 drops a minute. Thus the patient receives three quarts of milk and 15 grams of sodium bicarbonate per day. Such a solution will theoretically neutralize nine quarts of decinormal hydrochloric acid. Certain obvious difficulties in the treatment will be avoided if the following procedures are added: (1) Accustom the patient to the tube by doing a day and night fractional test meal first. (2) After forty-eight hours of the drip, study the chemistry of the blood; if the alkalinity approaches 80 volumes per cent or if the symptoms of alkalosis appear, decrease the alkali. (3) Use sedatives, luminal during the day and a hypnotic at night. (4) For dryness of the throat, allow an occasional sip of the mixture. As adjuvants to the treatment local heat is applied to the abdomen and atropine, 1/75 to 1/150 of a grain, is administered by mouth or hypodermic three times daily. The tube is allowed to remain in the duodenum for two to three weeks. Then it is removed during the day, and the patient is given the conventional ulcer therapy. Among the features worthy of comment in the author's series of 42 cases were the loss of all symptoms in four to six hours after the institution of the drip, the complete comfort of the patient while on the drip, and his willingness to return to the treatment on the recurrence of even slight symptoms. -American Journal of the Medical Sciences, May, 1933, clxxxv, 5.

On Pain.—As so little is known concerning the mechanism of the production of pain, David

Waterston carried out observations for the purpose of ascertaining what the tissues are in which it can be excited, the nature of its recep tors, and the peripheral pathways by which the impulses travel which give rise to the sensation of The general procedure was that a sharp needle was introduced through the skin and passed to underlying tissues-muscles, tendons, periosteum, into the walls of veins and arteries The observations recorded have disproved the theory that pain might be due to overstimulation They show that in the skin the pain apparatus is distinct and separate from that for touch proof of this was afforded by showing that it was possible to shave off a layer of epiderinis, for example, from the tips of the fingers, without causing any pain, in spite of the fact that the terminals of the nerves of tactile sensation were divided This finding has a bearing on the much disputed problem of peripheral sensibility and especially on Head's theory of its mechanism. There is now no doubt of the correctness of Head's views of the separateness, anatomically, of the tactile and the pun mechanisms of the surface of the body The prin apparatus which responds to the widest range of stimuli and which is the most sensitive is that of the corinm where it is apparently intimately connected with the nerves accompanying blood vessels and especially the capillaries The deeper tissues of the body can as a rule give rise to pain, and arteries especially are a source of acute pain from mechanical stimulation seems strange that arteriosclerosis may transform the walls of the arteries into degenerated tissues without producing pain. The walls of veins are much less sensitive to mechanical stimulation than those of the arteries Muscles have a pain ap paratus which is usually excited by a special form of stimulus 1e, spasmodie contraction, as in cramp, or by contraction with impaired blood supply Pain is usually regarded as a protective mechanism and as being primitive in character, but it is a more tughly specialized sense than would at first appear. The cornin is furnished with nerves responsive to a wide range of stimuli -in other words, protective against many injurious agencies The tissues lying deeper also have a pain apparatus, which in the case of arteries re sponds to mechanical injury, but in muscle is responsive rather to harmful conditions originating in the muscle than to mechanical injury Pain is not a sensation produced by nerves of other forms of sensation but has its own apparatus its own nerves, and probably its own receptors -The Lancet, May 6, 1933, ccxxiv, 5723

The Etiology of Grip—The grip epidemic of 1933 says H Schter, writing in the Munchener medizimscher Wochenschrift of April 7, 1933, raised anew the question as to the exeiting agent of this disease, which Pfeiffer's discovery in 1891

seemed at that time to have settled. Even before the War, Kruse expressed doubts concerning the rôle played by the influenza bacillus as an agent pointing out that this bacillus was never observed by anyone during the 1889-90 epidemic, and that at a later time it was more frequently observed without having any relation to a chincal influenza as for example in measles, whooping cough, etc. The hope that the great grip epidemic of 1918 19 would answer the question of its etiology was doomed to disappointment, it seemed rather to confirm Kruse's view, for very few influenza bacilli were found. Even in the Pfeiffer Institute in Breslau they were encountered in the sputum m only 51-76 per cent of the cadavers Meyer has rightly pointed out, one single proved case of grip in which the influenza bacilli are not present destroys once and for all the theory that these microorganisms are the sole cause of grip The negative results of experiments in mice during this year's epidemie led to the same conclu-Pfeiffer himself in 1920 took up the state ment that influenza bacilli are present almost obiquitously in all kinds of disease and in healthy persons too with great regularity, and admitted that if this were true it would dispose of the sigmificance of the influenza bacillus as the primary exciter of pandemic influenza. He believes there are chronic cases which produce the spread from one epidemie to another, but that no ubiquitous distribution has ever been demonstrated raises the question whether the great pandemic scourges separated from one another by many intervening years could have developed from these influenza bacilli commonly found in the healthy The supporters of this theory take refuge in the assumption of an increased virilence of the bacilli and a decreased resistance on the part of the public. It is hardly to be supposed, however, that widespread pandemics can arise out of such endemically present exciters It would be more rational to conclude that pandenue grip and its exciter ought to be separated from smaller epidemics for which the name influenza might be retained. A search should be made for a still unknown and probably invisible filtrable virus, but thus far all such attempts have failed

Infection and Resistance in the Upper Respiratory Mucosa—C S Linton, writing in the Laryngoscope, April 1933, xlin 4 calls attention to the fact that the mucous membrane of the upper respiratory tract must be regarded as a complicated mechanism which may be affected adversely or favorably by many factors from the outside world. In order to evaluate the relatinal importance of these various factors he has correlated the observations of various investigators. He attacks the problem from the standpoint of infection and resistance. The factors of importance in natural resistance to infection of the

upper respiratory mucosa are mucous secretion, ciliary action, phagocytosis, lysozyme, local reaction, natural immunity and local immunity. Each of these factors is not only accessory to the others but dependent upon them, for the full realization of its function. The mucociliary layer is marvellously efficient in its action and must be considered as the first line of defense, while phagocytosis and other factors, although showing some surface activity, constitute second and third lines of defense. Many influences tend to impair the natural resistance of the mucosa. The most important of these are: diet and physiological effects, including chilling, ventilation, chemical irritation, metabolic fluctuations and obstruction of drainage, also allergy and trauma. In regard to diet Linton calls attention to studies showing that in vitamin A deficiency there is an atrophy of the lining cells of the trachea and bronchi, while epithelial metaplasia is not common. Vitamin B deficiency seems to lead to respiratory infection. All of the other factors are likewise important in the sense that any one may be the limiting factor in causing a break in the defense of the mucosa. It is impossible to separate local factors of decreased resistance from systemic factors, since the respiratory tract seems to be a favorite site for the manifestation of decreased systemic resistance.

Infection is not only dependent upon factors operating in the host, but also upon certain properties of microorganisms. The most important of these are: the production of toxic products, capsule formation, adaptibility to environment, and ability to lodge in intercellular spaces. That great variation in the virulence of many strains of bacteria occurs cannot be questioned. All of the above properties of bacteria are probably quite variable and depend upon the particular environmental conditions. Toxic products of bacteria may be considered as an extending arm which reaches far out beyond its immediate environs. Capsule formation and adaptability are protective phenomena for the bacterium in its struggle against the host. Ability to lodge in intercellular spaces is a little understood phenomenon which must exist, however, in order for a bacterium to penetrate an apparently normal mucosa. It may be partly the result of properties of the bacterium and partly the result of changes in the host. Electrochemical and interfascial tension phenomena may be of importance in this connection.

The Present Position of Manipulative Surgery.—Philip Wiles, writing in the Practitioner, May, 1933, cxxx, 5, calls attention to the greatly enlarged scope of manipulative surgery in recent years, and discusses minor injuries which respond well to manipulation. The actual lesion in these

cases is not a "bone out of place," but the endresult of some strain or misuse of the affected part, as, for example, the man who finds his wrist locked in the dorsiflexed position while making a stroke at golf. What has occurred is that the lubricating synovial fluid has been squeezed from between the opposing joint surfaces; separating them by manipulation will effect a cure. chronic back strain a cumbersome support merely aggravates the trouble. The treatment is mobilization by manipulation with the patient under an anesthetic, but never until an x-ray examination has been made. In manipulating the sacroiliac joint the patient is placed on his left side, near to and facing the edge of the table. The left leg is allowed to hang over the edge of the table and is steadied between the operator's legs. The right arm is placed forward and the left backward, so that the body is twisted. The operator grasps the patient's left arm near the shoulder with his left hand and his right arm lies along the crest of the ilium, with the elbow over the sacroiliac joint. With a rotary movement the patient's left arm is forced backward and the pelvis forward and downward, so that the trunk is twisted and the ilium is rotated about the sacrum. If the case is a severe one massage should be started at once, applying heavy, deep work. In acute painful back and acute stiff neck the immediate relief afforded by manipulation is sometimes startling, and this treatment makes bed rest unnecessary. In treating foot strain it is well to remember that the tone of the muscles is of prime importance. Immediately it is lost the ligaments are called upon to maintain posture; this injures the ligaments and causes adhesions. Very stiff feet should not be mobilized at one sitting, as the reaction is so severe that the patient cannot maintain the correction.

It is much better in most cases to repeat the manipulation several times. Foot exercises should be instituted as a part of the daily routine. When arthritis is the cause of painful feet, there must be no mobilization during the acute stage of the disease. In this condition stock-size arch supports are useless; very careful fitting of the whole shoe is necessary. In knee-joint strain there is no need to stop weight-bearing unless a ligament is severely damaged. The manipulative treatment must be energetic from the start. In case of injury to the semilunar cartilage, manipulation may be tried after the first attack, but if the trouble recurs the cartilage should be excised. minor exceptions tennis elbow is the only condition around the elbow which calls for manipulation, and the results of this treatment are not uniformly good. With the patient under an anesthetic the movements which had been found to produce pain should be carried to their extremes.

LEGAL

HOSPITALS-POWER TO DISCIPLINE PHYSICIANS ON ITS STAFF

By LORENZ J BROSNAN, ESQ

Counsel Medical Society of the State of New York

The power of the authorities of a hospital to exclude certain physicians or surgeons from its staff, has a number of times been the subject of litigation. A leading case on this subject carried to the Court of Appeals illustrates the principle involved.

The hospital in question was a membership corporation which derived its meonie in part from amounts paid by patients, from endowments and charitable gifts, and also from public moneys received from the city in which it was located It had been approved by the State Board of Charities. The affairs of the hospital incre minaged by a board of directors. The hospital liad a set of by-laws which could be changed only by a vote of its members, and also a set of rules and regulations adopted by the directors inhich could be changed at any time by the board.

A certain doctor who was a member of the corporation and of its visiting staff, and who resided and practiced in the city where the hos pital was located, became involved in a series of differences and disputes with those in active charge of the hospital. In the report of the case there is no suggestion that there were any charges of illegal or unethical practices on the part of the doctor. The board of directors passed a resolution dropping him from the visiting staff. The secretary of the hospital by letter notified the doctor that he had been dropped, with the privilege of continuing to treat at the hospital such patients of his who were at that time confined at the hospital. The doctor brought suit against the hospital in equity, seeking to nullify the resolution of the board of directors and to enjoin the carrying out of the order barring him from the hospital The lower court decided in favor of the aggrieved doctor, but the Appellate Division of the Supreme Court reversed this ruling and sustained the action taken by the hospital The Court of Appeals affirmed the latter ruling without opinion

In deciding against the contentions of the doctor plaintiff, the Appellate Division handed down a decision which is worthy of comment. The plaintiff had taken the position that the defendant was strictly a public corporation, the court refused to so hold. Public corporations, according to the court, "are the instrumentalities of the State, founded and

onned by it in the public interest, supported by public funds and governed by managers deriving their authority from the State." The defendant hospital on the other hand, the court ruled, was a corporation organized by permission of the Legislature, to undertake similar duties, it was a private corporation, supported mainly by voluntary gifts, and engaged largely in charitable work for the benefit of the public, it still remained a private institution even though it received a donation from public funds, and even though it would be exempt from liability for negligence and evenipt from taxation. In tuling that the hospital had been within its rights in the action it had taken, the court said.

"The selection and retention of physicians to treat patients admitted to the hospital are matters of judgment and discipline power to appoint usually implies the authority to remove. In common experience instances are not imusual where some physician disagrees with hospital management. When such disagreement becomes so pronounced as to interfere with orderly management and discipline, and when there is persistent violation and disobedience of necessary rules and regulations, we think the directors may bring the inharmonious conditions to an end by summary action They are not required, in our judgment, to give notice and conduct a trial in every such case Public-spirited citizens, usually having business of their own, who act as directors without pay, having many duties relative to finance and management, would no doubt find their time fully occupied if the duty of holding trials on all sorts of complaints were superadded. If in every detail of minagement involving the relation of the hospital with the physician and patient, they have no power of final decision but must be guided and directed by orders and judgments of the court therein, then their duties are little more than perfunctory"

The court said further

"The law does not require a corporation like defendant to furnish its services and accommodations to every one who applies, whether patient or physician. There can be no absolute right in individuals to claim the benefit of its privileges. Such a thing would be impossible

There must be discretion vested in the management to make selection from applicants with regard to accommodations available. It may reject one who has some trivial ailment, and accept another whose needs are greater. This is not illegal discrimination depriving a person of his rights; nor do we deem it such discrimination if from a large number of physicians it selects members of its visiting staff with regard not only to their medical skill, but to their adaptability to the rules and discipline of the institution."

The court suggested that if the plaintiff had received unjust treatment, his remedy was not with the courts but to bring public opinion to exert pressure in his favor upon the institution. The opinion said:

"The usual remedy for persons dissatisfied with the internal management of corporate affairs is to elect a new board of directors. If the acts of the directors are generally regarded as arbitrary and unjust, contributions, without which the hospital cannot operate, will be withheld; and public opinion, the most potent regulator of public affairs will furnish the remedy."

In another State some years ago, where a somewhat similar set of circumstances were presented, the court ruled in a similar manner. In that case also, the hospital was managed by a board of directors empowered, according to the court, "to adopt any regulation for the government of the hospital which is reasonable and consistent with the general purposes of the corporation." A by-law was passed that only physicians who comply with the code of ethics of certain medical associations could practice in the hospital. The plaintiff in that case, seeking a decree to compel the directors to permit him the privilege of treating patients at the hospital, had indulged in public advertising in his medical practice. He had issued circulars wherein he promised cures and boasted of his knowledge, skill and success. The court found that the hospital had acted within its rights in enforcing its by-law against the physician. It was stated by the court that the plaintiff's practices were in flagrant disregard of the standards of his profession and were unprofessional and discreditable. The court said:

"The requirement of the by-law was reasonable and within the power of the directors to adopt, and we think entirely right and proper."

In certain of the States in which the laws regulating the practice of medicine are not so stringent as in New York, other problems have been presented as to the power of a hospital to restrict the membership of its staff. A most noteworthy case was a few years ago

carried to the Supreme Court of the United States to test the question. The case arose in one of the southwestern States, the State Constitution of which included a provision that "The Legislature may pass laws prescribing the qualifications of practitioners of medicine in this State, and to punish persons for malpractice, but no preference shall be given by law to any schools of medicine." plaintiff was an osteopathic physician who was duly licensed to practice medicine in the The board of managers of a certain municipal hospital, maintained by a city in conjunction with the Medical Department of the State University, had made regulations excluding osteopathic physicians from practicing in the hospital. The osteopath sought to enjoin his exclusion from practice in the city-maintained hospital, and the case was taken to the Supreme Court on the ground that the osteopath had a constitutional right to practice his profession in a hospital maintained by the State or a political subdivision thereof. The court held against his conten-

tions, saying in part in its opinion:

"It is argued that if some physicians are admitted to practice in the hospital all must be, or there is a denial of the equal protection of the laws. Even assuming that the arbitrary exclusion of some physicians would have that legal consequence in the circumstances of the case, the selection complained of was based upon a classification not arbitrary or unreasonable on its face. Under the State Constitution and statutes, anyone who shall 'offer to treat any disease or disorder, mental or physical, or any physical deformity or injury, by any system or method or to effect cures thereof,' is a physician and may be admitted to practice within the State. We cannot say that a regulation excluding from the conduct of a hospital the devotees of some of the numerous systems or methods of treating diseases authorized to practice in the State, is unreasonable or arbitrary. In the management of a hospital quite apart from its use for educational purposes, some choice in methods of treatment should seem inevitable, and a selection based upon a classification having some basis in the exercise of the judgment of the State Board whose action is challenged, is not a denial of the equal protection of the laws.*** The limitation of the provision (the Constitutional provision above quoted) is obviously directed to the qualifications of those to be admitted to the practice of their profession in the State, and has nothing to do with the qualifications of those who are to be allowed to practice in a State hospital or to participate in an educational enterprise conducted by the State."

SUBGLENOID DISLOCATION OF HUMERUS

A doctor engaged in the general practice of medicine was called to attend a middle aged woman at her home. He was given a lustory of her having had a dizzy spell, and fallen, injuring her right shoulder. She was a fleshy woman weighing about 180 pounds. The doctor examined her shoulder but was unable to note any affectence in its continuity or to determine any specific injury. She complianed of her shoulder hurting on extension. He told her that in order to make a suitable examination she should allow an 1-ray examination to be mide of the part.

The doctor saw her again the following day and was unable to detect anything further. He again requested an r-ray evanilation which was refused. He did not see her again until about two weeks later when she called at his office for some medicine. She answered in response to questions about her arm and shoulder that they were 'first-rate'. However, about ten days thereafter she again came in complaining of pain about the shoulder, and the doctor again advised 1-rays to be taken. She then had 1 rays taken.

and a subglenoid dislocation of the right humcrus was disclosed. The next day the doctor together with a surgeon reduced the dislocation under an anaesthetic by manipulation. An 1-ray picture, taken after reduction, showed the same to be completely reduced but that there was some slight thickening of the capsule, which prevented the head of the humerus from settling back to within three-sixteenths of an inch of its normal position. The patient rapidly regained the use of her arm and her functional result was excellent.

She brought suit against the general practitioner charging him with negligently failing to discover and properly set the dislocated shoulder. The plaintift claimed that by reason of the alleged negligence she had suffered great pain, an unnecessary operation and impairment of ability to move the arm. The action was brought on and tried before a judge and jury. At the close of the testimony introduced on behalf of the plaintiff a motion was made on behalf of the defend ant for a non-suit which was granted by the court, thereby terminating the matter in the doctor's favor.

MALPRACTICE CAUSE OF ACTION BARRED BY THE STATUTE OF LIMITATIONS

A married woman about forty-five years of age was sent by her family physician to a specialist in gynecology and obstetrics for possible operation. The doctor examined her and a diagnosis of ovarian cyst and possible uterine fibroid was made. Since she was a large woman and possibly a bad surgical risk, he put her in the hospital for several weeks, where she underwent a course of diet and treatment to prepare her for the operation. As soon as her condition appeared to be favorable for operation, the doctor under a spinal anesthesia opened her abdonien and found a small filiroid tumor and a large cyst of the left ovary. He performed a supravaginal hysterectomy and also removed her appendix.

The patient lind a very smooth and uneventful recovery, and in about three weeks was able to leave the hospital in good condition. About a month later, when the doctor examined her at his office, he found that the wound had entirely healed and that she was apparently cured.

After sometime had elapsed, the doctor instituted suit in the City Court to recover his bill for professional services which had remained in paid. The patient put in an answer denying the value of the services that the doctor had rendered After the case had been three years on the cal-

endar waiting its turn for trial and as it was about to be reached, a motion was made by the attorney for the defendant patient for leave to serve an amended answer in which the defendant sought to include a counterclaim alleging malpractice. The City Court Judge denied the motion ruling that the Statute of Limitations had run against any cause of action for malpractice which the patient might have had, and that therefore the amendment could not be permitted.

Thereupon the patient instituted a Supreme Court action against the surgeon, setting forth as a cause of action for malpractice the same facts which she had sought to set up as a counterclaim in the City Court action. The doctor's attorney then made a motion in the Supreme Court for Judgment dismissing the patient's cause of action on the ground that the City Court Judge had already determined that any cause of action based on alleged malpractice was barred by the Statute of Limitations, and that said ruling was conclusive in the Supreme Court action. Upon receipt of the motion papers, the attorney for the patient agreed, in order to save his client the costs which would be imposed by the Court, to discontinue the Supreme Court action and to settle the City Court action by proments of the doctor's bill

NEWS NOTES

COMMITTEE ON PUBLIC RELATIONS

The regular monthly meeting of the Committee on Public Relations of the State Society was held in the Albany office on May 29, 1933. There were present Drs. Sadlier. Johnson Hambrook, Cunningham and Ross; also the Executive Officer, Dr. Lawrence.

Venercal Disease Clinics:—A letter was read from Dr. E. McD. Stanton of Schenectady regarding the clinic facilities for the treatment of indigent cases of syphilis, objecting to the two-page article published in the Health News of the State Department of Health under date of May 15, 1933, on the subject "How cities are caring for indigent cases of syphilis. This article begins with the following statement:—

"When should a community have a clinic? Generally speaking, a clinic should be organized when a community can care for its indigent syphilities at less cost by providing clinic service than by paying physicians a nominal fee per visit for the medical supervision of such cases."

The article then gives tables for seven counties, mostly rural, showing that the annual cost of efficient treatments in those counties would be from \$6,000 to \$13,000, while it would be only \$1,000 or \$2,000 on a county clinic basis.

Members of the Committee questioned the desirability of publishing the figures, and stated the general principle that other considerations were as important as economics in deciding the method of treating indigent syphilitics.

While the committee felt that it was not in a position to take formal action, its members were favorably inclined toward the following principles:—

- 1. The field of the State Department of Health in venereal diseases is that of education rather than treatment.
- 2. Physicians object that the responsibility for treating syphilities be transferred from competent practitioners to the State Department of Health.
- 3. Physicians are willing to do what they can to stamp out venereal diseases.
- 4. Efficiency rather than economy is the proper basis for judging any plan of treatment.
- 5. Diagnostic clinics should be continued in larger places because it may well be that clinics have greater facilities for diagnosis than every doctor has for diagnosis. However,

not every facility is necessary in every case in order to make a diagnosis or carry out efficient treatment.

The committee voted to refer the subject of venereal clinics to the chairmen of the two committees—that on Public Relations and that on Public Health and Medical Education.

The Hard of Hearing:—A communication was received from Dr. Wendell C. Phillips of New York, asking the help of the Committee on Public Relations regarding plans for more adequate examination of the hard of hearing. It was decided to grant an audience to the New York League for the Hard of Hearing, consider its plans, and help to work out methods for more adequate examination of the hard of hearing, and that Dr. Emily A. Pratt of the State Education Department and Miss Estelle E. Samuelson of 480 Lexington Avenue, New York City, be invited to attend the next meeting of the Committee on Public Relations.

Examination of School Children:—Regarding the relation of the family physician to the examination of school and pre-school children, letters were read from Dr. Haake of Homer, New York, about the lack of facilities in schools for adequate examinations, the lack of opportunity to follow up defects, and the insufficient salary of physicians for making satisfactory examinations. Dr. Haake called attention to the "folly and uselessness of the present examinations which discover only the grossest defects, but do not correct them; and only subject the child to a wrong impression of a health examination and give the idea that it is of no value because nothing is done about Dr. Haake suggested that abnormalities." two courses might be followed, either the total discontinuance of these examinations in communities where they are doing more harm than good both to the child and to the medical profession; or the establishment of a system which will function satisfactorily.

A letter was read in reply from Dr. William A. Howe of the Educational Department, referring to the letter from the State Medical Society regarding school examinations, commending it as stimulating fresh interest among physicians. He believes that with the cooperation of the medical profession of the State there will be ultimately worked out a satisfactory system of health service in schools. Dr. Howe deplores the low salary paid for school

examinations, and the lack of facilities in

These letters were referred to the chairmen of the Committee on Public Relations and on Public Health for further consultation

Dr Lawrence reported that this subject was of increasing interest in the District Branches Dr Lawrence was asked to write to Dr Daniel Reilly, Commissioner of Health in Cortland County, in which Homer is located to take the matter of school examinations in that county into consideration, and to undertake to bring about a satisfactory situation there

After further discussion it was decided to stand by the principle of the family pliysician's relation to all school work, and to undertake to encourage the family pliysicians of the State to undertake pre-school work. After considerable discussion Dr Lawrence was asked to communicate with the officers of the State Parent Teachers' Association, and the secretaries of the County Medical Societies regarding this whole subject of the relation of the family pliysician to school work, and the cooperation of the State Health Department in providing adequate facilities

County Nuises -A letter was read from Dr J D Olin of Watertown regarding the public nursing situation in Jefferson County service in Jefferson County has been discontinued by the Board of Supervisors because of the ex-Dr Sadher's reply to Dr Ohn's lutter was read, in which Dr Sadher said that the Committee on Public Relations would try to think up some way of solvin gibe public nursing situation in Jefferson County The members of the committee felt that they are compelled to balance the necessity of certain health services against their cost, but on the other hand the curtailment of necessary services should receive the unqualified disapproval of the medical profession

It was decided that the Chairmen of the Committees on Public Relations and Public Health should advise the Committee on Public Relations of the Jefferson County Society

Public Welfare Relief —There was a long discussion regarding the future status of the Special Committee of the State Society on Temporary Emergency Relief. The committee approved the leadership of the Special Committee in State aid for the medical care of the indigent.

A report on the Buffalo City Hospital dispensary plan was considered and endorsed

There was a discussion of the status of the relation of the profession to the medical administration of public welfare in Washington County (See this Journal, May 15, 1933, page 663) It was decided to seek further in formation regarding the county

There was a discussion of the medical administration at the Lowville State and County Hospital. It was decided that informal friendly advice was the best course to follow.

Crippled Children—A letter was read from Dr. Sherman M Burns of Oswego regarding the compensation allowed by the State Department of Health for the after-care of crippled children and a letter in reply from Dr Sadlier that the matter would be presented to the Committee on Public Relations After a long discussion the Secretary was directed to write to Dr Burns that the Committee on Public Relations is considering a fee bill

State Physicians in Private Practice—The State Department having charge of prisons is taking steps to eliminate the private practice of medicine by full-time physicians in the State employ, the delay being caused by obligations already assumed in rural sections adjacent to State institutions

W H Ross, Secretary

DISPENSARY ADMISSIONS IN MONROE COUNTY

The June News Letter of the Medical Society of the County of Monroe is given over principally to the Report of the Joint Committee on Dispensary Admissions by the Rochester Hospital Council The News Letter prints the full report, and comments on the recommendations as follows—

"This report had previously been approved by the Countia Minora and the membership of the Society is published in full. It constitutes a most important document which should be carefully studied by every physician. Provision is made for the permanent functioning of the plan agreed upon. The report illustrates the determination of all interested to develop a cooperative undertaking, having in mind the best interest of the patient, the medical profession, the hospitals, and the community as a whole. It illustrates also the fact that physicians are the medical advisers to the community as well as to the sick individual. The functions of an out patient department are outlined, new policies agreed upon, and a definite classification of patients made. Good is bound to result."

The full report follows --

REPORT OF JOINT COMMITTEE ON DISPENSARY ADMISSIONS

Functions of an Out-Patient Department:-The Committee conceives that the functions of an out-patient department or dispensary are to provide:

1. Adequate medical care for all persons who cannot afford to pay for the services of a qualified physician.

To cooperate with doctors and to provide teaching facilities for graduate and undergraduate physicians, nurses, and dietitians.

3. To provide investigation into the causes and cure of disease, i. c., rescarch.

New Policies Adopted:—To provide these ideals, the out-patient departments of Rochester hospitals and dispensaries have agreed to adopt the following policies:

1. Admission. All hospitals and dispensaries will adopt and follow the same general plan of determining admissions, which will be recorded on cards similar to the one outlined below.

O.P.D. Financial Data

Classification Family Name Address No. in Family Legal Residence Unit No. Scrvice Occupation Income

Father Mother

Rent

Insurance Savings Dependents

Referred by Address Family Physician Address Other Clinics Attended Organization Aiding

Worker

(Reverse of Admission Card)

I certify that the statements recorded above are correct, that I understand the law relating to the treatment of patient in Out-Patient Departments, and that I cannot afford to pay a private physician for required scrvice.

The Out-Patient Department is to provide medical

care for those who cannot afford to go to a doctor.

The Law provides as follows: (Section 296, Chapter 55 of the Consolidated Laws.) "Any person who obtains medical or surgical treatment on false representations from dispensary licensed under the provisions of this article, shall be guilty of a misdemeanor and on conviction thereof shall be punished by a fine of not less than ten dollars and not more than two hundred and fifty dollars." (Imprisonment until fine be paid may be imposed. Code Criminal Procedure, Section 718.)

Signed.....

All applicants shall be asked whether they have a family doctor and whether they have been recently under the care of a doctor. If either question is answered in the affirmative:

(a) They shall be requested to return to that doctor and bring from him a recommendation for admission to the Out-Patient Department. Latitude must be allowed Admitting Officials in the enforcement of this policy.

(b) If the condition of the applicant demands immediate attention, the Admitting Officer shall try to com-municate with the doctor by telephone and obtain rec-

ommendation for admission.

(c) If the doctor cannot be reached, the patient will be given temporary admission and a letter sent to the doctor reciting the facts and requesting a reply within five days, whether he approves of the admission of the patient to the Out-Patient Department, and if not,

whether he will continue treatment himself.

Financial Eligibility:—The following table shall be used as a guide in determining eligibility as regards

income:

One in family	\$12.00 per week
Two in family	20.00 pcr wcek
Three in family	22.50 per week
Four in family	
Five in family	27.50 per week
Six in family	
Seven in family	32.00 per week
Eight or more in family	4.00 per capita per week

Income should represent the entire amount received from all sources, earnings, rent, board, ctc. It should include entire earnings of employed children, not merely the board paid. Families having incomes above these limits are expected to go to private physicians. Admitting Officers should take into consideration income, size of family, type and probable length of sickness, ability to work after recovery, etc. Exceptions may be made necessary by reason of expensive and lengthy treatment.

The incomes in the guide are generfally sufficient to allow patients to pay all routine Out-Patient Department and Dispensary fees.

No arbitrary point can be fixed at which fees shall

be remitted; circumstances in individual cases must govern these decisions.

The financial status of all patients shall be redeter-

mined at least every six months.

Ineligibility. If an applicant is found to be ineligible by reason of greater income than the regular schedulc allows and has a family physician, he shall be referred to that physician, but if he has no family physician, the Admitting Officer may recommend for consideration the names of at least three members of the hospital staff most competent to attend to the patient's sickness. For those hospitals having salaried staff members, who have no offices outside the liospital, it shall be the understood policy that only the names of staff members having out-side offices shall be given. If the patient comes from outside Monroe County, the names of staff members having offices in the hospital may be included.

Staff members having offices in such hospitals may, however, see patients who come to them, either as regular consultation cases, i.e., sent by another physician, or who come to the hospital asking specifically for a certain

doctor.

Patients sent to the hospital with a written request from a physician that his patient be directed to that member of the staff best suited to attend to his care may also be referred to staff physicians having offices in the building.

2. Out-Patient Departments shall not be expected to furnish consultation service for private patients.

Each Out-Patient Department and Dispensary agrees to adopt a schedule of maximum charges, as follows:

	=
a.	Diagnostic visit (first visit) \$.50
b.	Treatment visits (re-visits) \$.50
c.	Laboratory chargesat cost
đ.	X-ray chargesat eost

An effort will be made to adopt uniform charges for like service.

Applicants who can afford to pay more than the maximum schedule of charges will be referred to private physicians, as stated above.

3. Private medical practitioners shall agree to treat patients who, because of their financial standing, are eligible, and also those who, because of their financial standing, are ineligible for admission to an Out-Patient Department, for fees within the means of the patients referred to them.

4. Patients who are financially able to employ the services of a private practitioner and who refuse to do

so will be denied treatment by the dispensary.

5. Every effort shall be made to prevent "shopping" and patients will be transferred from one dispensary to another only upon request of the transferring dispensary 6 Medical supplies will be dispensed according to the melude drugs, Medical supplies following policies surgical apparatus glasses and false teeth

Classes of Patients to be considered include acute,

sub acute, and chronic cases

A For those patients who are known to private welfare agencies and who are being cared for by private hospitals it shall be considered the duty of the Hospital to provide all medical supplies for acute cases but it shall be understood that the Hospital may expect the Social Agencies to assist in the provision of expensive medicines, drugs for chronic cases and surgical appa-

Those patients who are receiving aid from the В

City Welfare Department

1 Hospitals may rightfully be expected to assume the responsibilty for the provision of drugs for acute Theoretically this might be argued to be a re cases sponsibilty of the City Practically, it is so evidently for the welfare of the Community to have it handled promptly by the Hospital that theory must give may to practicability

2 For chronic cases requiring continued medication it is suggested that a plan be worked out with the Wel fare Department whereby prescriptions may be written in duplicate by the physician stating the amount of mediwhich this medicine may be expected to be re-ordered

3 Cases requiring surgical apparatus glasses etc should be taken up individually between the Hospitals and the City Welfare Department

C Representatives of the Board of Education and the Family Agencies shall work out a plan to secure glasses for children whose families are not receiving relief and cannot provide the needed glasses

7 Public and private welfare organizations are requested to conform with the above regulations and in making direct references to private practitioners shall follow the procedure laid down herein for dispensary financial investigators

8 A permanent joint committee composed of representatives of the Hospitals and the Medical Society shall be established to which all matters of common interest relating to Out-Patient Departments Dispensaries and Hospitals shall be referred

The membership of the permanent Joint Committee is as follows Dr Sol J Appelbann Chairman, Wiltiam T Nolan Secretary Dr Nathaniel W Fason Dr Christopher G Parnall Dr E T Wentworth, Dr A M Johnson, Dr David B Jewett

SARATOGA COUNTY

The regular meeting of the Medical Society of the County of Saratoga was Iteld on May 18, at Saratoga Springs, with over two hundred physicians present, including guests from the surrounding counties of Albany, Rensselaer, Fulton, Schenectady, Montgomery, Warren, Washing ton, and Hamilton The guests also included Dr H Flaherty of Syracuse President of the Medical Society of the State of New York, and Dr Alexander Lambert, past president of the State Society, and of the American Medical As-Morning and afternoon sessions were held, with a limelieon at noon and a supper at the close of the meeting

The morning session was held at the Lincoln Bath House on the State Reservation, and the

program was as follows -

'The Geology and Chemistry of the Mineral Waters", by Mr Herbert Ant, Chemist of the State Reservation

"The Saratoga Waters in Cardiae Disorders", by Dr Carl R Comstock, Saratoga

Springs
3 "The Waters in Gastro intestinal Condi tions", by Dr Edward J Callahan, Saratoga

Springs

"The Waters in Disorders of Metabolism", by Dr. Walter S. McClellan, Saratoga Springs

The physicians were shown through the State buildings given over to Therapy, and methods of the use of the water were demonstrated

The afternoon session was held at Newman's Lake House, Saratoga Lake, at which the follow ing program was given -

"The Nature and Prevention of the Com plications of Diabetes', by Dr Elhott P Joslin, of Boston

"Grave Colitis of Unknown Etiology', by Dr John L Kantor, New York City

THE DAILY PRESS

LOWERING BIRTH RATES

One hundred and fifty years ago Matthews was deeply concerned about over-propulation, and pointed the value of war in keeping the number of a people down to the capacity of the land to support them. The New York Herald-Tribune of June 14 has the following editorial argument in favor of fewer births, with a better quality of children.—

"A whole new field for sociological speculation is opened by the figures on this country's declining birth rate that have just been given out by the government's statisticians in Washington. They say that the average last year for all parts of the country was the lowest in nur history and that it will be lower this year. From this they deduce that we are not far from the point where our population will stand still and that, since we now live much longer on the average, we shall shortly be a nation of elders with sedate tastes, about which industry and the commercial arts had better be foresighted.

"Because of ancient tradition, and particularly because of the Anteriean liabit that dates from pioneer days of applauding every form of expansion, our people are likely to look upon a slowing up in the growth of our population as an evilomen. It always has been so. In ancient times, when nations were constantly at war, patriotism was gauged by the size of families, and a decline in the birth rate was a sure sign of national decadence. This tradition was very strong in Rome and was passed into all the Occidental peoples

as a political axion. The conditions under which the idea was sound are gone, but the tradition persists

"In this country we were once in great haste to develop a population that could occupy, open and defend a huge virgin territory. Then we wanted communications over it all and an independent industrial system, at a time when there were few auxiliaries to min power. All these linge jobs are now virtually done. The continent is conquered and its defense is assured. Our problem is, therefore, no longer that of enlisting sufficient man power, from any source and of any quality, for a campaign of conquest, but that of keeping our man power occupied in useful, self-supporting and self-respecting enterprises."

"Under these changed conditions there would be no more promise of future wealth, health and happmess for the American people in a high birth rate, indicative of nothing but the nonselective multiplication of our numbers, than in unrestricted, non-scleetive immigration In a lower birth rate, on the other hand, we can see some hope that a sense of responsibility for the health, education and opportunities of the next generation is coming to govern the social thought of the present one. We can see some promise of selective rather than quantitative growth Viewed in this light, the lowering of the birth rate is surely a form of natural selection to meet a demand for intelligence, which becomes more insistent yearly, instead of a demand for numbers

COST OF EMERGENCY CASES IN HOSPITALS

The people expect a general hospital to take emergeney cases, but they do not realize that the care of these cases costs money, and that the financial burden on the subscribers to the hospital deficit is like that on the physicians when they give free eare to the poor. The New York Times of Jime 23, commenting on this burden uses the Flower Hospital of New York City as an example and says.

"Eighty per cent of its patients last year were treated free or at far less than cost. Its ambulances respond to nearly 1,000 emergency calls each month. One thousand patients each week are being treated in its emergency rooms and clinics, and several thousand "imemploved sick" were brought back to health within its walls. But with over 12,000 individuals on its lionor.

roll of contributors in other years, less than 3,000 gifts were received during the past twelve months most of them for reduced amounts

New York City paid \$57,357 to Flower Hospital last year for the eare of the destritute sick but this service cost the hospital \$115,000. In addition thousands of dollars were spent in its clinics and wards for those who could pay but a part of the cost. Last year's deficits were met by several large gifts to general funds which can not be expected again this year. This is an emergency case for which immediate treatment is sought."

Practically every general hospital in New York State is in a similar financial condition. Is support by taxation the only practical solution of the problem of hospital finances?

ECONOMICS

The following letter printed in the New York Times illustrates the confusio nof the average citizen, including the doctor, when he tries to reason out the economic state of our country:—

"John Doe owes a mortgage and has an equity in an insurance policy. He is a debtor and a creditor.

"If he deflates he increases the value of his invested money but loses his home. If he inflates he pays off his mortgage but loses his savings. He can preserve the value of his insurance equity and lose his equity in his home, or he can repudiate his mortgage debt and lose his investments.

"Had he not gone in debt there would have

been no opportunity for the investment of his savings, and had he not saved he could not have borrowed money to build his home.

"The more money he saves, the bigger becomes his debts, and if he pays off his debts the only use he can have for money is to spend it. To avoid being a spendthrift he must borrow money, and to be financially sound he must only borrow money to expand, and what is the use of expanding if he does not spend more. His investments are his own debts. He has got to go in debt to be thrifty. He is the richest guy in the world with \$200,000,000,000 invested at interest, and the poorest guy in the world trying to pay interest on that amount of debts."

A MILLION DIPHTHERIA IMMUNIZATIONS

The Department of Health of New York City takes advantage of a possible news item in order to educate the people regarding preventive medicine. The New York Herald Tribune of May 17 contains the following editorial comment on the act of immunizing the millionth child against diphtheria:—

"Long life to Mary McDermott, nine months old on May 3! She can tell her grandchildren that she was the millionth New York child to be immunized against diphtheria and that the pioneers of the preventive treatment, Dr. William H. Park and Dr. Bela Schick, took part in the proceedings.

"The inoculation of the millionth child, how-

ever, should not lead the public to an undue feeling of security. There still are nearly 500,000 children under six years old in the city unprotected against the disease; and the greatest danger from diphtheria is in the first five years of life. In a number of smaller cities where all parents can readily be informed, so that they will take the precautionary measures, diphtheria has been virtually wiped out. The task of education in New York is great, but not overwhelming, as the results thus far prove. 'With a little more effort,' said Dr. Park on Monday, 'there will be as little diphtheria in the city as smallpox. The goal is in plain sight of mothers and fathers in New York.'"

WRITTEN RELEASE FROM LIABILITY

The New York Sun of June 7 comments editorially on a general release after an accident and its effect on a malpractice suit against the attend-

ing physician:-

"When a person is found liable for damages for personal injury he may be liable also for medical negligence, mistake or lack of skill in the treatment of the injured, on the theory that the original injury was the proximate cause of the subsequent damages. This doctrine is sustained by a number of authorities in New York State. An extension of the principle was declared recently by Justice Heffernan of the Supreme Court, sitting in Schoharie county, who said that he had been unable to find precedents covering the question before him.

"A seven-year-old girl was struck by an automobile truck, her leg being severely injured. When she left the hospital the owners of the truck settled the claims of her father and herself for \$7,884 and received a general release. Immediately thereafter the father brought suit seeking \$110,000 in damages on behalf of himself and

the girl against the hospital and the surgeon who attended the child. There was no allegation that the surgeon did not treat the injury according to his skill and ability, but, conceding malpractice, Justice Heffernan said that recovery was precluded.

"The owners of the motor truck were liable not only for the injuries the girl sustained but also for the alleged malpractice of the attending surgeon and for the expenses of medical attendance. Having that liability in view they settled with the claimants. The child had already suffered the effects of any malpractice that had been committed, and this cause of action could have been enforced against the original wrong-The release having been made in settlement of all existing claims, the plaintiffs could not bring a second action for malpractice against the surgeon who occupied something of the position of a joint tort feasor. While the court found no rule on this exact question in New York State, he cited many decisions in other jurisdictions where he said the rule seems to be well settled."

BOOK REVIEWS

DISEASES OF THE NISE, THROAT AND EAR FOR PRAC-TITIONERS AND STUDENTS. Edited by A. LOGAN TURNER, M.D. Third Edition. Octavo of 465 pages, illustrated. Baltimore, Williams & Wilkins Company, (William Wood & Company), 1932. Cloth, \$600.

The different branches or specialties of medicine are so interdependent that one who is practicing any one of them must have a fair knowledge of several others The general practitioner or specialist who wants to know how and where the discases of the ear, nose and throat are related to his field of medicine, and wishes to learn of the recent advances made in pathology, symptoms and methods of treatment of these diseases, will find this book a valuable one. It was written primarily for the practitioner and the senior medical student. However, those confining their work solely to diseases of the ear, nose and throat, will find much in it of value. The author, Dr. A. Logan Turner, and those associated with him in producing the volume, are connected with the Hospitals and the University of Edinburgh.

This, the third edition, has been thoroughly revised and brought up to date. The chapters on Pernral Endo scopy and Meniere's Symptom Complex have been entirely rewritten.

Each chapter is very complete and, although con densed, makes the subject very clear. The illustrations and plates cannot be praised too highly. They are very distinct and they explain the text unusually well.

The index, a valuable part of any reference or text hook, is very complete.

There is an appendix with ten pages of formulæ which adds much to the value of the book.

In every respect it is a work that can be highly reeommended. JOHN W. DURKER.

PICTORIAL MIDWIFERY. By COMYNS BERKELEY, M.D. Sceond Edition. Octavo of 172 pages, illustrated Baltimore, Williams & Wilkins Cumpany (William Wood & Company), 1932. Cloth, \$3.00.

Intended as a manual for midwives, this is a picturebook with only just enough reading matter to explain book with only just enough reading matter to explain the illustrations. A beautiful colored plate shows peraphigus neonatorum. Positions of the fetus are shown as first, second, third and fourth, in the English manner, but should not the third be second? The midwife should be increased with the second? The midwife should be impressed with the great frequency of right posterior positions; it would improve her obstetrics. The fetal circulation is explained in great detail because "Pupil midwives find it very difficult to understand"; but to what useful purpose this knowledge may be put is not apparent. A good bnok which meets the indi-CHARLES A. GORDON.

RADIOLOGIC MAXIMS. ADIOLOGIC MAXIMS. By HAROLD SWANDERG, M.D. 12mo of 127 pages. Quincy, Ill., Radiological Review Publishing Company, 1932. Cloth, \$1.50.

This little book tells more truths, concisely stated, relative to X-ray and Radium in diagnosis and disease than any text book we have read. It includes the statements that have appeared from time to time in the litera-ture of such authorities as Bloodgood, Ewing, Kelly, Wm. Mayo, Yung, Moynihan, Burnam, Morris, and others concerning the advantages of radiation therapy for various pathological states. various pathologic states.

Specially does it stress the radiotherapy treatment of epitheliomata, cavernous angiomata, menorrhagia of puberty and the climacteric, fibroids, carcinoma of the cervix, hyperthyroidism, and palliation in metastatic as well as inoperable malignant states.

The maxims are so numerous, truthful and full of knowledge, we feel this small book should be read by all; as a review for the informed radiotherapist and to open a vista for the uninformed practitioner it is worth its weight in gold.

There are but one lundred and twenty-two pages, the reading is light and the dividends in knowledge heavy MILTON G. WASCH.

PRACTICAL OBSTETRICS FOR STUDENTS AND PRACTITION-ERS. By P. BROOKE BLAND, M.D. Octavo of 730 pages, illustrated. Philadelphia, F. A. Davis Company, 1932. Cloth, \$8 00.

This is a text book intended to be not too small and not too large. It is like other text books in the arrangement of material, but contains a particularly valuable chapter in obstetrical jurisprudence. Another section containing good references for additional reading should he an excellent guide for the student who is auxious to go a little further into obstetrics. Colored plates are excellent, and our new knowledge of menstruation and hormones is very well presented. It is too bad that pictures of the old infant-swinging method of resuseitation are included, the new and better methods of inducing respiration in the new born are not mentioned. A good text book, CHARLES A. GORDON.

THE HISTORY OF DERMATOLOGY. By WM. ALLEN PUSER, M.D. Octavn of 223 pages, illustrated. Springfield, Ill., Charles C. Thomas, 1933. Cloth, \$3.00.

This well-printed book covers the history of Dermatology from ancient Egypt to the beginning of the twentieth century. It is the first history of Dermatology and Syphilology in English. The specialty is covered thuroughly; as is its background in medicine in general. The various workers are given eredit for their principal enntributions and the presentation is made in such a manner as to be very readable and enjoyable. Dr. Pusey has covered a long overlooked field in the literature of Dermatology and is to be commended for the manner in which he has done it. JOHN C. GRAHAM.

THE FAILING HEART OF MIDDLE LIFE, BY ALBERT S. HYMAN, M.D., and AARON E. PARSINNET, M.D. Octavo of 538 pages, illustrated. Philadelphia, F. A. Davis Company, 1932. Cloth, \$5.00.

This is a carefully prepared, well-written volume on the heart of middle life. The subject is presented in six parts containing fifty-five chapters. A clear presennation of the cornnary circulation in health and disease, including coronary sclerosis and thrombosis is given in Part 1. A discussion of the various conditions of cardiac muscle dysfunction is presented in Part 2. authors prefer the term of myocardosis to the term myocarditis. Further discussion of coronary thrombosis and occlusion, together with the symptoms, prognosis and treatment is found in Part 3. The electrocardiographic findings in degenerative heart disease are shown clearly in Part 4 Chest pain, or angina pectoris, is discussed in Part 5, with the latest methods of treatment both medically and surgically. The medico-legal aspects of sudden death from heart disease are presented in Part 6. This is an excellent and thorough exposition of the subiect, and will be useful to all who study this volume. A bibliography of 1,250 articles on the subject is added.

HENRY M. MOSES.

OUR NEIGHBORS

ANNUAL MEETING IN LOUISIANA

The New Orleans Medical and Surgical Journal for April records the cancellation of the annual meeting which was to have been held April 25-27, in the following editorial:

"It is deeply to be regretted that it has been found necessary on account of the present unsettled economic condition throughout the State and the country to postpone indefinitely the Annual Meeting of the State Society, which was to be held this year at Lake Charles. The unfortunate series of circumstances which have arisen in the financial world make this a necessary step. This was decided upon by a written vote of the members of the House of Delegates. The vote was practically unanimous. The delegates felt that the meeting would be so slimly attended and would be confined almost entirely to the physicians living around Lake Charles, and hence it would be unwise to go to the expense of putting on the annual State convention.

"The House of Delegates of the State Medical Society has done a wise thing, but nevertheless

one can not help but feeling that this unfortunate but necessary postponement will leave void in the year's activities of the profession throughout the State an empty space which will be hard to fill. The Annual Meeting presents a series of excellent scientific presentations which is good for all of us to hear. The social aspect of the meeting is as important; it brings the doctors together; it makes them acquainted with one another; and it encourages the proper fraternal spirit which is often difficult to cultivate and more difficult to achieve. Most of the physicians who are regular attendants at the Society's State meeting derive a great deal from it, and to them, at least, its absence this year will be a real sorrow, mitigated in large part by the fact that it would be a very serious drain on their resources were they to attend the meeting.

"We know that the Lake Charles physicians will be disappointed, but we know furthermore, that they will approve of the action taken by President Harrison and the House of Delegates."

EDUCATIONAL COMMITTEE IN ILLINOIS

The Illinois Medical Journal for March contains the February monthly report of the Educational Committee of the State Society. The following abstract will show the scope of the work of the Committee:

Radio: Forty-seven radio talks were given from WGN, WJJD, WAAF, including twentyfour talks during the Young Mother's Hour given every morning.

The topics of the talks included the following: Reducing Children's Nuisance Values.

My Child Won't Eat.

Kidney Stone.

Functions of the Nose.

Unconsciousness.

Nervousness. Speaker's Bureau: Forty health programs were arranged for lay groups as follows:

Parent Teacher Associations.

Women's Clubs.

Business and Professional Groups.

Men's Club.

Public Community meetings.

Farmers Institute.

Scientific Programs for County Societies: The programs for county societies were arranged. Some of the subjects were as follows:

Nephritis of Pregnancy.

Pelvic Infections with Movies of Operations.

Endocrinology.

Pediatrics.

Pernicious Anemia.

WYALIN

A Biliary Stimulant

Contains No Phenolphthalein

Pancreas, Common Duct, Portal Veln and Duodenum are shown through the Phantom (transparent) Stomach

BILE SALTS—Natural cholagogue. The only true cholagogue which stimulates the liver to secrete bile. The bile thus formed is Nature's Laxative—very mild and harmless in its action. Assists in the absorption of fats and regulates the intestinal flora.

EXTRACT NUX VOMICA—Stimulates gastric secretion and bowel action.

ENZYMES (LIPASE, TRYPSIN, AMYLASE) —Digest fats, carbohydrates and proteins in the bowel,

EXTRACT CASCARA SAGRADA— Increases tone and peristalsis of upper and lower intestines.

Wyalin is especially useful in biliary disturbances and is also of value in intestinal stasis and other bowel disturbances where a digestant and gentle laxative is required.

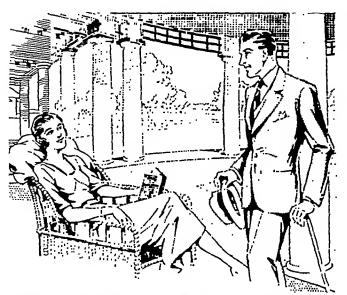

Supplied in bottles of 50 and 500 tablets.

May we send you a sample of Wyalin for a clinical trial test?

Control the integrity of your prescriptions by specifying Wyeth's pharmaceuticals.

JOHN WYETH & BROTHER, Inc. PHILADELPHIA, PA. AND WALKERVILLE, ONTARIO

Cardiac Therapy

at Saratoga Springs

This Spa is made possible by Saratoga's marvelous, naturally carbonated mineral waters. The values of these waters have been attested by such eminent scientists as Dr. Franz M. Groedel, the distinguished heart specialist of Bad Nauheim, Dr. Gustav Toepfer of Carlsbad, Dr. Paul Haertl, head of the Staatslaboratorium at Bad Kissingen, and Dr. Oskar Baudisch of Yale, formerly of the Rockefeller Institute. Characterized as the peers of any waters to be found in Europe, they are the only naturally carbonated mineral waters to be found in the United States east of the Rocky Mountains.

The Saratoga Waters are by no means the only reason for successful eardiae therapy at Saratoga Springs. Here the State owns and operates two beautiful and spacious bath houses. They have a combined capacity of 5000 treatments daily. They are fully and modernly equipped. In their pleasing, restful surroundings, an experienced staff of technicians under professional supervision, administer the baths and other collateral treatments such as massage, eabinet baths, colonic irrigations, douches, rubs and packs.

Members of the profession are eordiolly invited to be guests of the Stote at the baths while in Sorotoga. For complete information on the Sorotoga Baths and battled Mineral Waters, address: Medical Director, Saratoga Springs Commission, Sorotoga Springs, New York.

health meeting at Mendota.

Contact made with the Boy Scouts—hope to develop some health work with this organization before summer.

RESTRAINT OF UNLICENSED PRACTITIONERS IN WEST VIRGINIA

The May number of the West Virginia Medical Journal describes a unique method of proceeding against an unlicensed practitioner of medicine named Mitchell, whom the Court had failed to convict for violating the medical practice act. Dr. Raymond Sloan, of Huntington acting for the Cabell County Medical Society brought action against Mitchell on the ground that a license to practice medicine is a property right earned by each individual doctor. The article says:

"On this theory, Dr. Sloan petitioned the circuit court for an injunction against Mitchell to stop his medical practice. The petition set forth that Mitchell was infringing upon the right of Dr. Sloan and all other licensed physicians and surgeons in West Virginia, and should therefore be enjoined from further practice.

"The state supreme court upheld Dr. Sloan,

the syllabi reading as follows:
(Continued on page 849—adv. xiii)

(Continued from page 848-adv. xii)

'The right of a licensed physician and surnt to practice his profession is a valuable achiese in the nature of a property right to teet which he may sue in equity in the rest of himself and other physicians simply situated, to enjoin a person from enaching upon said right by engaging in the ctice of medicine and surgery without a te license.

'A court is not powerless to prevent the ng of an act involving encroachment upon uable franchise rights of others merely bese such conduct is denounced as a public

nse.'

The importance of this decision is farching, because it simplifies the legal steps necessary in the prosecution of quackery. Any licensed physician in West Virginia, under this ruling, may sue in equity for an injunction against any person practicing medicine without a state license. Heretofore it has been necessary to secure a grand jury indictment against an unlicensed practitioner and then go through a trial in criminal court.

"It is hoped that this new ruling will create an incentive to each county medical society in the state to rid its particular section of unlicensed quacks. The officers of the various component societies should see to it that this is done. The supreme court ruling is a matter of state-wide interest, but the application of the ruling is an individual matter for each individual county society to handle for itself."

LEGISLATION IN WYOMING

The Wyoming section of the April issue of larada Medicine contains the following commits on medical legislation in Wyoming:

Senate File Number Six corrected an error our medical practice act. This law had been the statute books for over thirty years—yet

in no place did it say "a doctor must have a license to practice medicine in the State of Wyoming." It only required that any one wishing to practice medicine in Wyoming. "should apply for a license." Senate File Number Six corrects this

error and puts teeth in the old law. It was passed and signed by Governor Miller. The passage of this law will now enable the State Board of Medical Examiners to see that the law is enforced, and it marks the completion of a program to correct the weak part of our medical law.

"A law was also passed making it a legal requirement that the state Board of Medical Examiners shall have one osteopath as a member. For years there has been a gentlemen's agreement to this effect and one member has been an osteopath. This law was supported by the doctors to show good faith, and the Governor has appointed an osteopath, Dr. Tarrant of Laramie, as a member.

"A bill was introduced to amend the present law on marriage to require the female also to be examined and have a doctor's certificate of freedom from venereal disease, as is now required of the male before a license to marry could be issued. The Committee on Public Policy and Legislation recommend that such a law be passed or the old law repealed. The legislature killed the new bill, so we are still operating under the clean male and unclean female law as of old. We fail to see the justice of such a one-sided law. The fine sentiment of chivalry must have been the real reason why this law was killed. However, had the lawmakers all been doctors the law would have been passed, because doctors have seen some unclean things in life.

"Next month we hope to continue the review of the acts of the past legislature and refer to some other bills that were introduced and killed. Taken as a whole the past session was one of the best sessions we have seen for several years so far as good honest work and honest effort to cut down the expenses of State Government."

TICK VACCINE IN WYOMING

The Wyoming Section of the May number of Colorado Medicine describes a meeting of the State Board of Health and the appointment of County health officers, and then described the following action in regard to tick fever:

"The Board requested all doctors who have been furnished the Government Tick Vaccine free not to charge more than one dollar per person for their services. This action was taken because of the limited supply of vaccine and because as a rule most of those exposed are the ones who have been out of employment a great deal and are unable to pay a normal fee. If any doctor has vaccine he is not using, the Board requests that he return it to his County Health Officer so that every drop can be used this year, as it is evident that there will be a demand for vaccine beyond the government's capacity to supply it."

PROPERTY RIGHTS OF MEDICAL PRACTICE IN WEST VIRGINIA

The West Virginia Medical Journal of June contains an editorial comment on a court order restraining an illegal healer from practicing medicine on the ground that he was intringing on the property rights of the licensed physicians. The editorial says:—

physicians. The editorial says:—
"Mitchell, a Chiropractor turned Naturopath, located in Huntington about one year ago and began a series of extravagant and misleading advertisements in the Huntington newspapers. His advertising material was so flagrant that the Cabell County Medical Society, in an effort to protect the public, brought Mitchell to trial for practicing Medicine without a state license.

This effort failed. The Society then applied to the circuit court of Cabell County for an injunction against Mitchell. This new move went to the state supreme court and, late in March, the supreme court held that a license to practice medicine was a property right, to protect which any physician could sue in equity on behalf of himself and his fellow practitioners.

"In the final decree of the Cabell County circuit court, we quote the following articles restraining Mitchell from:

"(a) Diagnosing . . . any human ailment, in-

firmity or affliction by any method or mar

"(b) Treating or prescribing treatment for any human bodily or mental ailment or sick ness by any manner or means whatsoever whether or not such treatment involves the administering or prescribing of drugs of similar agency, or the performance of any surgical operation.

"(e) Giving advice to any person suffering from any ailment or sickness upon any cours of conduct or any rule or manner of living to be followed by any such person for the benefi of improvement or preservation of such per son's mental or physical health.

"(d) Opening or maintaining an office for the purpose of doing at such office any of the acts herein prohibited and enjoined.

"(public in any way
his ability or right to
treat any sick or attricted person in any manner whatsoever, or his readiness, willingness
ability or right to do any of the acts herein
prohibited and enjoined

"(f) Charging or receiving in any manner whatsoever, any fee, compensation or reward of any kind for doing or purporting to do any of the acts herein prohibited and enjoined."

as possible in proportion to their numerical OSTEOPATHS IN MAINE HOSPITALS

strength in this state."

fitness. This law also removes the provision that no school of practice is to have a majority on the board as representation is 'to be given to the different schools of practice as nearly

The Maine Medical Journal of March carries he following editorial on the admittance of osteolaths to practice in the hospitals of Maine:-

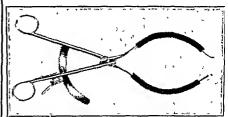

"With the amendment of the new draft of B. P. 109, L. D. 208, regulating the distribution of public funds to hospitals, it would seem that The right of the governing boards of our Maine # hospitals to determine the qualifications of the practitioners of the healing art necessary for Ithose who may practice within the several insti-Itutions under their control has been finally estabfilished and with no penalties attached. Amendment A reads:

"'All hospitals in this state which receive any public funds appropriated to assist in the care of residents of the state shall, subject to the approval of the boards of trustees of the respective hosht pitals, admit osteopathic physicians who are in at good standing and licensed to practice obstetrics and surgery according to the laws of the state to treat therein their own paying patients in private rooms, provided, however, that any such hospital may, at its option, set aside certain rooms therein for the use of such patients as an osteopathic unit,'

"This might well be called a bit of 'Joke Legislation.' It leaves the osteopath, or any other cultist, in the same position in relation to our hospitals as he has always stood. It emphasizes and recognizes the right of the governing boards to discriminate against any practitioner of the healing art whom they may consider unfit to admit to the privileges of their institutions. The osteopath, the chiropractor, the regular, the homeopath may one and all be debarred, if, in the opinion of the boards of trustees, they are unfit. are confident that the directors of our hospitals will not lightly sacrifice their ratings with the National Hospital Association, the American Medical Association, and such bodies as the Col-

A CLAMP TOURNIQUET

(Davised By Harry Cohen, MD, FACS)

At last a simple, efficient instrument to replace the inconvenient and troublesome common Tourniquet. The only Tourniquet that can be applied and removed in a few seconds. lege of Surgeons, by admitting any practitioners, however they may style themselves, who cannot comply with the standards which, in their capacity as directors, they have agreed to maintain.

"The bill, as first drawn, and which we are ashamed to have to state was supported in committee by four Senators, was a particularly vicious one-an outstanding example of the type of legislation continually urged by selfish and unthinking minorities. It served no public good and actually menaced the integrity of our hospitals. The amended bill, as passed, has its dangers, but if our hospital boards are true to the duty im-

COMMITTEE ON PUBLICATION .

Societies of New York State as a model for Ohio.

"In a recent issue of *The Survey*, Dr. H. Jackson Davis, medical director of the New York State Temporary Emergency Relief Administration, described the workings of the emergency relief law of New York, with special emphasis on the provisions relating to the furnishing of medical care to the needy.

"The method used in New York to provide relief for the needy and unemployed differ as to detail from those in effect in Ohio. However, in the final analysis, the programs are similar in that the primary responsibility rests with local communities for carrying out the objectives.

"Because of this, Dr. Davis points out, many of the county medical societies of New York State have formed special committees to confer with local commissioners of relief for the purpose of discussing questions of local and mutual interest.

"If such a plan has been found beneficial in New York State—and it has—from the stand-point of all concerned, patients, doctors and tax-payers—it may well be copies by the component groups of medical organization of Ohio.

"Obviously, most of the problems of medical relief to the poor of this state are essentially local. They differ according to the needs and resources of the various communities. A plan which meets the requirements of one city or county may not be adequate for those of an adjoining county. Local initiative and local responsibility must prevail to a large degree.

"Affected as it is by the emergency conditions which have arisen, the medical profession of Ohio has the right to a voice in how medical relief shall be administered to the needy. However, the question is one which must be met by the various county medical societies in cooperation with the welfare officials and agencies of their respective com-Frequent conferences between remunities. lief officials and representatives of the medicau profession in all counties undoubtedly would clear up misunderstandings, give both groups a better insight of the problems of each, and work to the advantage of all mutually interested in seeing that the necessary relief work is administered on a basis which is fair and equitable to all concerned."

MALPRACTICE SUITS IN OKLAHOMA

The Journal of the Oklahoma State Medical Association discusses malpractice suits in the following editorial:

(Continued on page 855-adv. xix)

(Continued from page 854-adv. xviii)

"Recently Oklahoma physicians, and probbly the same advice went to those in other tates, were advised that there would be an ncrease in premiums on policies protective igainst alleged malpractice, the rate now beng \$45.00, for a ten thousand dollar policy. t is said that the agents advised those conterned that the raise was due to increase in he number of suits brought in the state. It is significant to note that only a few years ago the rate was \$15.00 to \$18.00, then it was raised to \$25.00, now, due to the depression, no doubt, it has reached the present rather

high charge. Reading the petitions filed in these suits brings one to the positive conclusion that often the suit was a useless and unnecessary one to begin with. You cannot get blood out of a turnip, and especially, at this time of de-pression physicians should be unusually wary of bringing suits to collect fees, where, in many instances, a moment's reflection would show that all the physician would have, if he won his suit, would be a worthless, uncollectable judgment. Thousands of people, good yesterday, are 'bomb-proof,' today against any

sort of judgment, so, the physician should use a great deal of discretion, and know his judgment would be worth something, if he secured it. In some of these suits the defendant promptly counterclaims with allegations of malpractice. Whether such allegations are groundless or not the attorneys promptly take the view that he has a harder case to combat, and at once demands a larger fee, rather than his usual commission, from the physician who has placed himself in an embarrassing position. As a matter of fact it is well known that if the attorney goes ahead with his original intention to sue and get judgment upon a physician's bill, all allegations of malpractice are nullified, if the attorney gets judgment for the physician, despite the lugged in, twelfth hour allegation that the physician was guilty of malpractice.

"We would advise that suits only be brought when the claim is clearly just and the defendant vulnerable. Finally, in such cases friends are retained, not lost, if the case can be amicably settled between the parties most at interest-the patient and the physicianrather than have the matter go to a court of adjudication."

DIE MEDIZINISCHE WELT

Dr. Georg Zachariae,

"Therapie der rheumatischen Erkrankungen," (Therapy of the rheumatic diseases).

The author gives the following classification of the rheumatic conditions: (1) Inflammatory conditions of muscles, including Myalgia. (2) Rheumatic affection of nerves, especially the neuralgias, and sciatica. (3) Acute rheumatic joint lesions. (4) Chronic diseases of joints.—For all these conditions he contends that the primary and essential feature of the treatment should be hot brine baths, preferably sulphurous, at a temperature of 103° F. The chemical dissociation of the salts which occurs allows the free ions to penetrate the skin. After the baths it is essential that the affected parts should be covered with Antiphlogistine. -There is a definitive lowering of blood sugar after the baths, and the blood pressure also falls in consequence of an exertion of histamine bodies by the skin. Precautions must therefore be taken against collapse. As accessory measure mineral water of the Kaiser-Friedrich-Quelle are given the patient to drink daily.—Besides other cases, 79% of 124 cases of chronic infective poly-arthritis were cured.-Adv.

NEW SERVICE IN RABIES VACCINE, LILLY

Rabics Vaccinc, Lilly, V-776, heretofore available on order to the Lilly Laboratories at Indianapolis will hercafter be supplied through the drug This should be of particular trade. interest to all physicians because treatment for rabies is an emergency measure and it is important that it be instituted early.

This innovation is made possible by reason of the superior potency of the material even with a six months' dating.

The procedure is simple enough. When Rabies Vaccine is needed notify your pharmacist. He probably will have it in stock. Should be not have it he can secure it for you in a very short time. Lilly's Rabies Vaccine is supplied in 1 c.c. syringes ready for immediate use. The treatment consists of fourteen doses. In more than sixteen years failure in Lilly Vaccine has been recorded in but three cases and in each of these the lesions are said to have been about the mucous membranes of the face, a factor which is likely to hasten the onset of symptoms.—Adv.

PABLUM-MEAD'S PRE-COOKED CEREAL

Mcad Johnson & Co. arc now marketing Mead's Cereal in dried pre-cooked form, ready to serve, under the name of Pablum. This product combines all of the outstanding mineral and vitamin advantages of Mead's Cereal with great ease of preparation.

All the mother has to do to prepare Pablum is to measure the prescribed amount directly into the baby's cereal bowl and add previously boiled milk, water or milk-and-water, stirring with a fork. It may be served hot or cold and for older children and adults cream and sugar may be added as desired.

Mothers will cooperate with physicians better in the feeding of their babies because Pablum is so easy to prepare. It gives them the extra hour's rest in the morning and saves bending their backs over a hot kitchen stove in summer. Please send for samples to Mead Johnson & Company, Evansville, Indiana.—Adv.

CLAMP TOURNIOUET

Instructions for use of Harry Cohen Clamp Tourniquet.

Important: There are little refinements in the use of this Clamp which one develops after some practice and which adds greatly to the usefulness of this Tourniquet.

1. To apply, grasp Clamp with two hands, not one; between thumb and index finger on each hand.

2. Then release spring handle with another finger.

3. To use ratchet for fine adjustment it is advisable to first gently compress the clamp with one hand to release tension on ratchet and then wind or unwind adjustment screw with the other

4. To release Clamp when through do not spring release too suddenly but again compress clamp first and then release. Sec page xvii—Adv.

(Thyroid Crises)

By FRANK H. LAHEY, M.D., BOSTON, MASSACHUSETTS

PATIENTS with hyperthyroidism are able to be up and about in such a large percentage of the cases, even though they be considerably handicapped, that physicians readily come to believe that the disease possesses no real emergency dangers. Furthermore, family physicians seeing as they do a relatively limited number of cases of hyperthyroidism, may well go throughout their entire practice without ever having seen a case of acute hyperthyroidism, or at the most having seen but a limited number of such thyroid

This situation tends to make physicians feel that there is no real emergency as relates to

hyperthyroidism.

Dealing, as we do in this Clinic, with patients in large numbers who have hyperthyroidism, we are almost never without from one to several patients in the Clinic in varying degrees of acute hyperthyroidism. We are compelled to realize that when patients are permitted to progress into such degrees of intense thyroid intoxication that they are in thyroid crises, the danger of an imminent fatality is very materially increased, to say nothing of the added dangers of the operative treatment of such cases. It has seemed to the writer worth while to present some of the early indications of the possible occurrence of this state together with some of the measures which we have employed to overcome it when the condition

Typical cases are cited to present actual exam-

ples of this situation.

Case I. Mr. S. M. No. 30666. Mr. M. was seen by us on November 9, 1932. He was sixtyone years of age at that time and had had symptoms of thyroid toxicity over a period of three years, during which time he had lost fifty pounds. He had been nervous, very easily fatigued, and during most of this time had had a very good appetite. He had had several periods during which he had uncontrollable diarrhoea, and for two weeks before he was admitted to the New England Deaconness Hospital had had severe diarrhoea and had been delirious and disoriented.

During the first few days in the hospital he had auricular fibrillation and was continuously activated and confused. During the first week he was given continuous venoclysis by means of the continuous indwelling Hendon needle, and received on the average of five thousand cubic centimeters of fluids per twenty-four hours. This included one hundred and fifty grams of glucose by vein in a five per cent solution. He improved

During his second week in the hospital, he was out of bed for a short period each day and his treatment-Lugol's solution, high fluid, and high carbohydrate intake-was continued. His first basal rate was determined fifteen days after admission and was plus twenty-nine (note that one cannot depend upon either the basal metabolism rate or the pulse rate as dependable indications of the seriousness of the disease), his pulse was one hundred sixteen, his weight one hundred fifty-eight pounds. His diarrhoea was controlled by tineture of opium and intravenous fluids and glucose and gradually subsided until, at the end of two weeks, he had only two or three stools each day. He was given sedatives for his restlessness. After his diarrhoea had been controlled, his appetite improved and he was able to take large amounts of nourishment and fluids by

His thyroid was greatly enlarged and partially intrathoracic on both sides, the right side being the larger. His trachea was deviated to the left

and flattened on the right side.

In spite of his recent crisis, a left subtotal hemithyroidectomy was done as a first-stage operation three weeks after admission. He was placed on constant venoclysis for three days after this and his condition was good at all times. His basal rate six days after the first-stage operation was plus fourteen, his pulse ninety-six, his body weight one hundred forty-nine and a half pounds.

He returned to the hospital six weeks later, having gained thirty pounds in weight. metabolic rate was plus twenty-five, his pulse one hundred, his weight one hundred and seventy

pounds. He had taken ten drops of Lugol's solution each day in the interim and his second operation (right subtotal hemithyroidectomy) was performed immediately. His convalescence following this was normal and his basal metabolic rate six days after operation was plus fifteen, his pulse eighty-three, his weight one hundred and sixty-nine pounds. He has continued to gain and leaves this week, February 22, 1933, for a vacation in Europe. This patient illustrates a case rescued from a thyroid crisis, submitted to a two-stage thyroidectomy within three weeks of entrance, delirious and in a thyroid crisis, and relieved of his hyperthyroidism.

Case II. Mr. C. C. B. No. 24268. Mr. B. was fifty-six years of age at the time he consulted us on September 17, 1931. He was extremely weak and had had palpitation and loss of weight for four months. Emaciation, activation, weakness, and tremor were all present in a marked degree. His speech was slurring and at times he was delirious. The thyroid was about twice normal size, hyperplastic, and very firm.

He was admitted to the hospital and for several days was delirious and disoriented. He vomited for several days and could not take fluids by mouth. His basal metabolic rate was plus fortysix, his pulse one hundred twenty, his body weight ninety pounds.

He was placed upon continuous intravenous glucose and salt solution and subpectoral fluid and Lugol's solution. Ten days after admission his basal metabolism rate was plus sixteen, his pulse one hundred sixteen, his weight eighty-nine pounds. A few days later, he had a bilateral pole ligation and his basal rate was determined one week later. At this time the rate was plus thirty, his pulse one hundred and twenty-eight, his body weight eighty-seven pounds. His recovery after operation was very favorable.

He returned six weeks later with a metabolic rate of plus thirty-one, pulse one hundred twenty, weight ninety-one pounds, a gain of three and a half pounds in six weeks. A right subtotal hemithyroidectomy was done at this time and he was discharged with a basal metabolic rate of plus thirty-four, pulse one hundred twenty, weight eighty-six and a half pounds. He had a moderate reaction after the hemithyroidectomy with but slight temperature elevation and intermittent periods of auricular fibrillation.

Six weeks later he returned with a gain in weight of ten pounds, his body weight being ninety-six and a half pounds. His metabolism at this time was plus fourteen and his pulse eighty-eight. He withstood the left subtotal hemithy-roidectomy well and enjoyed an uneventful convalescence.

His last report shows that he has gained thirtythree pounds since his first operation. This patient likewise is a typical representative of this group of cases rescued from crisis, operated in stages, and relieved of hyperthyroidism.

Case III. Mr. C. O. No. 15344. This patient considered himself well up to a few months before we saw him, at which time he had begun to lose weight and feel a little run down. He still kept at work but with some difficulty. His friends began to comment later on the prominence of his eyes, which was a new development to him. He did not have any further symptoms of hyperthyroidism but six weeks before entering the Clinic the patient was taken with an attack of vomiting and indefinite abdominal pain. He was taken to a hospital in another part of the state where an appendectomy was done with a good recovery for one week. At the end of this time, swelling appeared bilaterally about the ears which, we presume, was a bilateral parotitis. Small incisions were made and pus drained from these, he stated, for two or three weeks more, at which time he was studied further to determine his thyroid function, since it had been noted for the first time then that a goitre was appearing on his neck. A basal metabolism was done, found to be elevated, and he was referred to this Clinic for operative treatment. His weight, during this time, had dropped from one hundred forty pounds to one hundred ten pounds.

Although this patient intended to be cooperative, his mental condition was vague, he was confused in answering questions, and it was felt that he could not be relied upon too closely as to the details of his statements. His basal metabolism on admission was but plus fourteen and I wish to call attention to the fact that patients in thyroid crises or on the verge of thyroid crises do not necessarily have to have marked elevation in basal rates. Note the first picture of this patient, Illustration I, with his marked emaciation, extreme exoplithalmos, and typical picture of acute hyperthyroidism, but with a relatively low basal rate. There appears with fair consistency a low basal rate during the time of impending crisis which later is elevated when the patients are gotten out of the crisis or following first-stage hemithyroidectomy and improvement in their general condition.

In spite of a low metabolism, it was obvious that, as one can see from the first picture, Illustration I, of this patient, no complete subtotal thyroidectomy could be considered. On April seventeenth, 1930, therefore, a right first-stage subtotal hemithyroidectomy was done with an excellent recovery. Two months after the right subtotal hemithyroidectomy, this patient returned for his second operation, at which time his basal metabolism had increased to plus fifty, he had gained twenty-eight pounds in weight, and was, as shown in Illustration II, markedly improved.

The left second-stage subtotal hemithyroidectomy was now done, resulting in a drop in metabolism immediately to plus thirteen. The last report on this patient, one year later, showed his metabolism to be plus two. His last picture is shown in Illustration III. His pulse rate was eighty to eighty-four and he had gained fifty-four pounds since the day of his entrance to the Clinic.

This patient, following his first admission to the hospital, was placed upon intravenous fluids and glucose and a high carbohydrate diet, and following each operation the same procedure was employed

ILLUSTRATION I

A patient with acute hyperthyroidism on the verge of thyraid crisis

This case likewise illustrates a patient on the verge of a thyroid crisis, kept out of it by active measures, operated upon within a short time, and relieved of hyperthyroidism. One has only to observe the first picture of this patient to realize the extreme degree of emaciation and intoxication which can occur in patients with acute hyperthyroidism.

These three typical cases were selected out of a large scries of patients either with crises or on the verge of crises to illustrate the seriousness of this state

Factors Bringing About Thyroid Crisis

The factors which precipitate a thyroid crisis are doubtless many and varied but since we have no accurate knowledge of what actually incites thyroid overactivity, we cannot construct any provable theory as to the real causes of thyroid crises

Once hyperthyroidism is established, however it is not difficult to comprehend how it may be so intensified that an acute hyperthyroidism or thyroid crisis results. Exophthalmic goitre or hyperthyroidism is a disease of excessive combustion. Patients with hyperthyroidism as a rule endeavor spontaneously to offset this excessive combustion by an in-

creased intake of fuel. As long as there is a relative balance between increased food and fluid intake and increased combustion, the symptoms of hyperthyroidism, while striking, provided there are no cardiae complications, are not alarming

ILLUSTRATION III

III to realize the sink and the degree of recovery which they can make following praper preparation and operative treatment.

and patients are able to be up and about accomplishing a considerable amount of activity, even though it produces a marked degree of exhaustion

If, however, fuel and fluid intake are not maintained in proportion to the excessive combustion and marked degrees of weight loss occur, the symptoms of the disease are strikingly intensified and the reaction to stimulation, particularly in the way of operative procedures, emotional burdens, and acute infections, is very much exaggerated. Dr. H. M. Clute has demonstrated, in a study of a group of cases in this Clinic, that marked weight loss, fifty pounds or over, in patients with hyperthyroidism, is an indication that they are serious operative problems as relates to possible mortalities and that operative procedures on such individuals must be done cautiously. These patients with extreme degrees of weight loss, represent a group in which hyperthyroidism is of an intense and serious character.

When hyperthyroidism becomes progressively intensified and fluid and food intake lags consistently behind, one then begins to observe the dangerous effects of excessive hyperthyroidism in a patient unprotected by adequate fluid and fuel intake. With excessive hyperthyroidism goes excessive combustion and when fluid and fuel intake is adequate to meet this excessive degree of combustion, progressive autocombustion occurs with exhaustion of available glycogen and diminution of the glycogen reserve in the liver. This state is associated with vomiting, diarrhoea, and delirium. What the vomiting and diarrhoea are due to, is not proven. Whatever their cause, they produce conditions well calculated to intensify the seriousness of the situation and to definitely increase the dangers of a mortality.

When vomiting or diarrhoea occurs in hyperthyroidism, a most undesirable situation has arisen because it is impossible for the individual in this state to take in the two necessary elements, fluids and fuel, to offset hypercombustion. When a patient vomits, this occurs. When he is able to take in food but has numerous liquid movements, loss of fluid and fuel likewise occurs and serious intensification of the symptoms results.

Hyperthyroidism in patients already suffering from this disease may be very dangerously intensified by emotional disturbances. We have seen two patients with hyperthyroidism die within four days as the result of serious emotional shocks. Both of these cases occurred some time ago, before we were as familiar with the management of this thyroid emergency as we now are, and were they to occur now, after an extensive experience with patients in thyroid crises. I doubt if fatalities would occur. Both cases occurred some years ago in patients while at home, after preliminary ligation of both thyroid poles, between the first and second stages of their operation. Both were subjected to extremely trying emotional strains, both immediately became nauseated, delirious, and went into crises and died with high temperatures and uncountable pulses.

We know that when acute infections are superimposed upon hyperthyroidism, the severity of the hyperthyroidism is often markedly and dangerously intensified and a thyroid crisis brought about. We have seen a man with but moderate hyperthyroidism become delirious and immediately progress into a thyroid crisis following the development of a tooth infection with alveolar abscess and high temperature. We have seen patients with moderate degrees of hyperthyroidism converted into serious and fatal cases by the complication of acute appendicitis or acute cholecystitis.

We know that anything which incites prolonged vomiting in patients with hyperthyroidism, diminishing thus their fuel and fluid intake, intensifies the disease and makes them candidates for an acute hyperthyroidism or thyroid crisis.

In an experience dealing now with approximately eleven thousand thyroid operations, we know that thyroid crises are not of common occurrence. During the year nineteen thirty-two, for example, one thousand and twenty-one thyroid operations were done on nine hundred and twelve patients and eight cases of thyroid crises occurred, two of which died. But one patient died following the one thousand and twenty-one operative procedures during the year.

That thyroid crises are not without a serious side is evidenced by the fact that in practically every year of our experience with thyroid disease a number of patients have come to the clinic in thyroid crises and have died unoperated in spite of all measures to get them out of crises.

When iodine first became popular in the treatment of toxic goitre, we were extremely optimistic that its employment in patients in thyroid crises would lessen the intensity of the disease, control its activity, and permit us to get these patients out of these dangerous states characterized by delirium, vomiting, and diarrhoea.

Iodine has usually not made it possible for us to accomplish this desired result when the patients are in advanced states of thyroid crises. We have learned, as the result of our experience with these cases, that if they are permitted to progress unopposed into these advanced states of thyroid crises, a majority will die in spite of all active measures to control the disease. We have also learned in our experience with these serious cases that if active measures can be undertaken before crises have progressed into advanced stages of intoxication, most of these patients can be kept out of serious thyroid crises and their vomiting, diarrhoea, mental confusion, and delirium can be cleared up as in the cases here They can be so prepared and improved with adequate measures, that surgery can be undertaken within two to three weeks of the time of the onset of the crisis.

It used to be thought when patients were seen

in thyroid crises, no surgery should be contemplated at this time, that they should be rejected as operative possibilities and sent home. It was thought that the mortality of operative procedures on patients in whom thyroid erises has been recent was so prohibitive that it should not be

undertaken As a result of a considerable experience with this condition now, we believe that this is not the proper attitude to take If these patients are in such severe degrees of hyperthyroidism that a crisis eventuates, even though one gets such a patient out of a crisis and sends him home the intensity of the hyperthyroidism has not been cheeked, the erisis can and frequently does re From this recurrent crisis it may not be as easy to extricate the patient the second time as it was the first We have, therefore taken the position that what one should do with patients who have been gotten out of thyroid erises is to then prepare them for operation and to apply some ae tive procedure such as hemithyroidectomy which will lessen or check the progress of the disease and so prevent them from progressing again into these serious states from which it is so difficult We feel, therefore, that when to rescue them patients have been delivered from states of acute hyperthyroidism or thyroid crises, they should be prepared for surgery over a period of two or three weeks, by large amounts of fluids and glueose (five per cent) intravenously, by the oral administration of large amounts of earbohydrates and by the employment of Lugol's solution, ten drops three times a day, and an active surgical attack upon the disease made in order that its progress may be cheeked and the danger of fur ther erises averted

Since the most serious eases of thyroid crises are those which have progressed into advanced states of acute hyperthyroidsm it is obvious that warning signals of the onset of these stages of hyperthyroidsm should be recognized early in order that active measures may be undertaken to keep them out of crises and overcome the dangers of the situation

One of the earliest signs of an impending acute hyperthyroidism is an unexplained increase in pulse rate. When a patient with definite exoph thalmic gottre has been running an average up and about pulse rate of one hundred and thirty to one hundred and forty and for no apparent cause shows a persistently increasing rate this is a definite indication of the danger of a threatening thy roid crisis.

When a patient who has been entirely rational begins to show vague transient but definite periods of irrationality this is also an indication of an impending thyroid crisis

When a patient develops comiting one may anticipate at any time the onset of a thyroid crisis due to the mability of such an individual to take

in fluids and food and so combat the effects of the increased combustion associated with the disease

When a patient has a definite diarrhoea, such a patient likewise becomes immediately a candidate for a thyroid crisis because of the fact that even though fluid and fuel be taken, they are rapidly lost as the result of the diarrhoea, the metabolic bilince is not maintained, hyperthyroidism becomes intensified, and the danger of a crisis imminent.

When a patient with a severe or even moderate hyperthyroidism develops any degree of infection, the hyperthyroidism may immediately become so intensified that he or she likewise becomes a cindidate for a thyroid crisis

It is obvious, then, that the salvition of patients with acute hyperthyroidism or thyroid crises is in the cirly discovery of the onset of this condition and the prompt employment of adequate measures to combit it

With no purpose of being critical toward nonsurgical methods of handling patients with hyperthyroidism, one should not undertake such methods without appreciating that during the period of such management an acute intensification of the hyperthyroidism can develop at any time must be interpated in certain of the cases and dealt with promptly

As has already been stated when the evidences of an impending thyroid crises as mentioned above are present, energetic measures are neces-

An intravenous needle of the type (Illustration IVc) described by Dr George A Hendon of Louisville, Kentucky, should be tied into a vein just above the ankle Illustration IVe The tub ing leading from the needle should be strapped down to the instep as shown in Illustration IVe The tubing running from the needle to the con tainer holding the salt solution and glucose should be sufficiently long so that the patient can roll about in bed without pulling on the needle. It is preferable to tie the needle into a voin in the ankle rather than in the arm or hand because those delirious patients move their feet less violently than they do their arms The long length of tubing attached to a high container permits quite free movement of the ankle even to rolling over without disturbing the needle. A hot water bug hung against the container and both wrapped with a towel provides sufficient heat for the solution. A drop bulh and thumb serew, as shown in Illustration IV1 and b, are interposed in the tubing, the former in order that the nurse may count the number of drops per minute entering the circulation, and the thumb screw so that the number of drops per minute mny be regulated *

^{*}Many authors have described the administration of constant intravenous fluids and no suggestion of any claim of originality is interval as to this method. It is illustrated and ildsecribed for the benefit of those unfamiliar with its employment.

The surgical fellows of the Clinic have had a large experience with the management of continuous intravenous administration of saline and glucose since it is employed so frequently in patients with thyroid disease, in patients with jaundice, and following gastric, colon, and rectum resections. They are responsible for the maintenance of the continuous intravenous drip of salt solution and glucose. Four days represents the minimum period of time over which continuous twenty-four hour intravenous drip is maintained

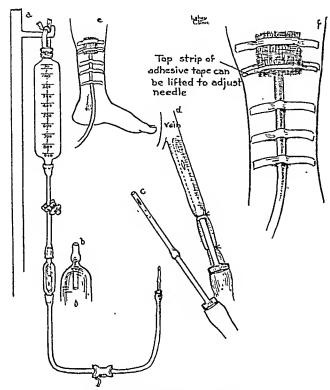

ILLUSTRATION IV. a,b,c,d,e,f.

The various parts of the intravenous apparatus for constant intravenous drip with the Hendon needle are shown together with the method of tying the needle in the vein, its insertion in the vein above the ankle, and the method of strapping the tubing along the leg to prevent pulling on the needle.

The container, thumb screw, drop bulb, and Hendon needle are shown in a, drop bulb in b, Hendon needle in e, needle tied into vein in d, the needle inserted in vein in leg above ankle and strapped down leg in e; f is a larger scale drawing showing how the adhesive can be raised to adjust needle.

None of this apparatus is new or original. It is illustrated for the benefit of those unfamiliar with this plan of constant intravenous drip.

oj constant intravenous artp.

without changing the needle and in a recent extensive gastric resection done by the writer the same needle ran continuously the twenty-four hours around supplying intravenous salt solution and glucose without clotting for eleven days.

They have learned that five per cent glucose is the highest percentage which can be employed without causing thrombosis of the vein into which the needle is tied.

Patients are able to take up from forty to sixty drops of the solution per minute. Some patients are able to take up more than others.

In the beginning of our experience with this method of constant administration of glucose and fluids intravenously, a small bulb with the drip pipette was inserted in the tubing with the result that the air in the bulb was quickly exhausted, resulting in stoppage of the flow and then thrombosis of the vein. Larger drip bulbs are now supplied by the manufacturers (Illustration IVa and b) so that there is a much larger air space in them with the result that they function much longer and more satisfactorily.

Intravenous fluids and glucose are administered to patients in thyroid crises just as long as any of the signs of thyroid crisis (vomiting, diarrhoea, mental changes, high pulse rates, and high

temperature) are present.

If patients are not vomiting, Lugol's solution, ten minims three times a day, is administered by mouth. If they are vomiting, we have learned that fifty minims of Lugol's solution may be put in one thousand c.c. of salt solution and this is administered either by hypodermoclysis or intravenously without danger. Restlessness is controlled by sodium amytal, grains three or nembutol grains one and one-half.

Diarrhoea is improved by the intravenous salt solution and glucose and tincture of opium is also employed in controlling this complication. As soon as patients are cleared of the evidences of acute hyperthyroidism such as vomiting, diarrhoea, and delirium, they are encouraged to eat, taking a diet rich in carbohydrates. They remain in bed most of the day but are encouraged to be up for an hour in the morning and an hour in the evening.

When these patients have been free from crisis symptoms for a period of two or three weeks, surgery is undertaken, care being taken that at the most no more than a subtotal hemithyroidectomy is done.

As has already been said, it has usually been maintained that subtotal thyroidectomy in patients in whom hyperthyroidism has recently been acute (crisis) is an extremely serious operation. Such has not been our experience. If these patients are properly prepared and properly treated postoperatively and if too much surgery is not done at one sitting, the mortality in them will be extremely low. As evidence of the truth of this is the fact that in the last five years three thousand six hundred and fifty-nine operations have been done upon two thousand seven hundred and sixty-two patients with toxic goitre. group there were twenty-one deaths, none of which were in patients who were operated upon after rescuing them from critical states of hyperthyroidism and preparing them for operation by appropriate measures. It is not possible to state

accurately the exact number of cases of thyroid crisis that occurred in these years as the borderline between what is merely a severe hyperthyroidism and what is a thyroid crisis is somewhat indefinite. It is evident, however, in a Clinic such as this, dealing with a good many patients with hyperthyroidism, that a definite number of these cases must be dealt with each year particularly when it is realized that our operative figures do not represent a selected group since no patients, no matter how sick or how toxic, are rejected (after proper preparation), all are operated

SUMMARY

Patients with hyperthyroidism should not be permitted to advance into states of acute hyperthyroidism (thyroid crises)

There are warning signs of an impending thyroid crisis—increasing pulse rate, irrationality and delirium, vomiting and diarrhoea, and a superimposed infection

Thyroid crises demand immediate emergency

measures—constant intravenous drip of salt solution and five per cent glucose solution the twenty-four hours around, the rate of introduction averaging from forty to sixty drops per minute, the administration of Lugol's solution by mouth, in the hypodermoclysis or intravenous administration of the salt solution, the control of diarrhoea and the control of activation

When patients have been rescried from the immediate thyroid crises, they can be so prepared for surgery that either pole ligation or the first stage of a two stage subtotal thyroidectonic can be done with safety. This checks the progress of the hyperthyroidism, crises are prevented from recurring, and in six weeks after the first-stage operation, the second-stage final subtotal thyroidectomy can be done with complete and, in at least unity per cent of the cases,* lasting relief from hyperthyroidism accomplished.

Clute, Dr H M, and Veal Dr J Ross 'The End Results of Surgery in Exophthalmic Goitre Journal of the American Medical Association Volume 99, pp 642 645 August 20, 1932

SOME ADDITIONS TO OUR RADIOLOGIC ARMAMENTARIUM IN THE TREAT-MENT OF ESOPHAGEAL AND LARYNGEAL CANCER

By WALTER L MATTICK, M D, BUFFALO, N Y

From the State Institute for the Study of Malignant Diseases Buffalo New York Burton T Simpson M D Director,

THE primary purpose of this paper is not to call attention to any radically new methods but to show two forms of applicators in addition to the usual metallic radion seeds, tubes and external radiation by teleradium therapy, and ligh voltage x-ray. Such additional methods place at the disposal of the radiologist more diversified procedures to suit the individual cases under consideration.

It is well known that many radiologists hesttate to implant radon seeds into the esophiagus in the region of the aorta, also that further down in the same organ the accurate placement of such seeds becomes increasingly difficult. Our experience has further taught us that we have gained little by surface application of radium tubes of light filtration as previously used, yet surface application seems logical in these squamous cell epitheliomas of slow growth and slight metastatic propensity, provided we use ample filtration so as to destroy the cancer cell and leave the normal cell relatively intact

Such end is best accomplished by making use of heavy filtration low intensity radiation continued over a long interval as advocated by Regaud. To meet this requirement, Guisez has devised and used a modification of the Dominic tubes which are put in place in the esophagus apparently in a bougie and left in place for 4 to 6 hours daily. This bougie method seemed objectionable from the standpoint of discomfort to

the patient in having to hold the bougie in place for so long a time so with the aid of our instrument maker, I devised a series of tandem tubes to accommodate 5 mgm cells of radium element These tubes can be lengthened or shortened at will and are interconnected at intervals by a ball and socket joint. The filtration of these tubes is the equivalent of 15 mm. Pt. Such tubes are put in place by the aid of the esophagoscope and left in situ with a cord attached to an eye in the This cord protrudes from the month upper end and is fastened on the patient's check by means of adhesive plaster The patient is placed in bed and kept quiet by hypoderinics of codein

Thus after preliminary study of the lesion by csophagoscopy and asce-taining its length by roentgenograms and bougierage, these tubes can be made up to any convenient length sufficient to cover the ordinarily encountered lesion and still extend a safe margin beyond, on to the normal tissue

Filtration was arbitrarily placed at 15 mm Pt equivalent because heavier filtration while very desirable seemed impossible on account of making a tube that could be introduced under direct vision into narrow stricturous lesions such as we often encounter in our patients

With this radium applicator it is possible to radiate lesions ranging from 1 to 2 cms up to 6 or 7 cms in length and I have considered a dose of 75 mgms hrs per 1 cm length as an

approximate surface dose. It will at once be apparent that such radiation is an advantage over seeding where generally only the upper end of the lesion can be attacked. This approximate dosage was determined by finding the time necessary to produce a skin erythema on surface application of such tubes to the lower right abdominal quadrant of a patient so treated. Here it was found that 20 mgms. over 4 cm. length, left in contact with the skin for 15 hours, produced in 16 days a mild reddening and in a month a desquamating epidermitis extending over an area of 2 to 3 cms. about the periphery of the tube.

When such a radium applicator is filled with element or emanation and put in place two or three times weekly by means of the esophagoscope and left in place over the lesion for from

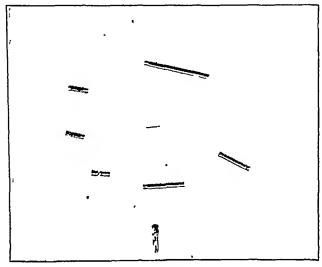

FIGURE 1

Showing unassembled csophageal tube. This tube can be made up to any suitable length to suit lesions of various lengths. The filtration is 1.5 m.m. Pt. equivalent and it can be conveniently loaded with radium cells (5 mgm.) or emanation in gold tubes.

20 to 24 hours each time, it is readily appreciated how we can achieve the ideal of prolonged low intensity radiation over long intervals of time.

Such treatment is not easy on the patients; in fact, is quite heroic. Guisez has reported some 5-year arrests after the use of Dominici tubes. It is just these optimistic reports that caused me to try similar tubes. The cases so treated seem to merit some consideration but it is too early as yet to report on them.

The accurate placement of these tubes in the esophagus can be further assured by fluoroscopy or roentgenograms of the chest taken with these tubes in position. Their removal is easily accomplished by gentle traction on the silk cord at the designated time.

I might add that treatment with this type of applicator is only applicable to lesions other than

those of the proximal end where some other type of radium therapy or seeding with gold seeds is more readily accomplished.

Next I wish to call attention to a gold appli-

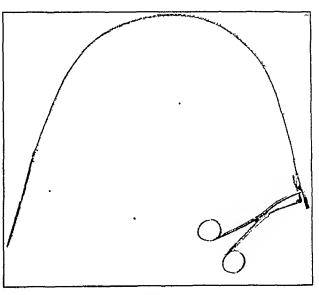

FIGURE 2

The assembled esophageal tube with the flexible introducing forceps and silk cord attached ready for introduction through the esophagoscope. For convenience of the photographer the introducing forceps is shown bent on itself rather than straight.

cator for the radium treatment of intrinsic lesions of the larynx.

This applicator is nothing more than a large laryngeal intubation tube with the airway con-

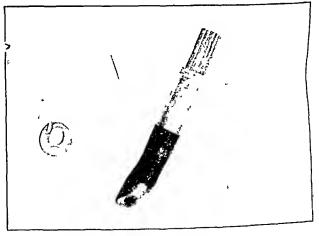

FIGURE 3

The unassembled gold intralaryngeal tube ready for loading with radon cells (5 mgm.) or emanation in gold. The filtration equivalent is 2 mm. Pt. Note the lower end of the tube is of hard rubber construction so as to reduce cost and weight.

centrically surrounded by a series of holes in which are placed radium element cells. The tube in shape is much similar to the usual O'Dwyer intubation tube and the idea is not original, the

writer having seen a silver tube of this type at the Veterans Hospital in Chicago. From these specifications I had a tube of 14 carat gold constructed for my use. This tube is moulded more to the shape of a laryngeal intubation tube as

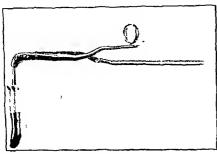

FIGURE 4

The assembled gold intralaryngeal tube with silken cord attached, ready for introduction into the larynx by means of the O'Dwyer introducer shown in place in the tube.

used for larvngeal intubation by O'Dwyer. The upper end of the tube unserews and presents in the lower piece twelve 1 m.m. concentric cylindrical holes equally spaced around the central airway so as to give a filtration of at least 2 m.m. gold. The cap, with a large airway hole in the center to match that of the lower piece, when screwed in place on this lower part, forms the upper expanded end of the intubation tube which prevents it slipping through the glottis. There is a small eye in the side of this screw cap through which can be threaded a braided silk cord which protrudes from the patient's mouth and is attached to the cheek or ear to facilitate easy removal as in the case of the esophageal tube. This tube is put in place in cases of intrinsic epithelioma of the larynx by the aid of the usual O'Dwyer intubation introducer along the left index finger hooked over the base of the tongue as in the usual technic for introducing a laryngeal intubation tube. After its introduction it is an easy matter to inspect the tube by mirror laryngoscopy to assure that the tube is in good position in the larynx.

Such applicators can be loaded with 120 mgms. of radium element consisting of 5 mgm. cells in each of the 12 cylindrical compartments. Emanation seeds could also be placed in these compartments if desired. This tube left in place for 4 hours yields 480 mgm. hrs. of exposure. Three or four such exposures will generally produce a pronounced epithelitis.

Only a few cases of intrinsic laryngeal epithelioma have been so treated to date. In each case a preliminary tracheotomy was done but it is possible that such cases could be treated without this preliminary operation in which case an emergency tracheotomy might be necessitated during the height of the reaction some 10 to 14 or more days later.

With the use of such an applicator one can be assured of an intensive radiation of heavily fittered gamma rays (2 m.m. gold filtration) delivered to the interior of the larynx over a fairly long time by a protracted dosage technic.

In using both the esophageal and laryngeal radium applicators as described here it has been the writer's custom to supplement such treatment by protracted heavily filtered (3 m.m. Cu.) x-ray or gamma ray telaradium therapy. This supplemental radiation therapy should preferably precede the internal application by a period of approximately one month, a dosage of the equivalent of 3000 to 4000 r's over 15 days can be given when using such heavy filters as above. After another month or two the usual high voltage x-ray through .5 m.m. Cu. filter can be given. At all times it is advisable to withhold or discontinue treatment by such protracted technic if a demonstrable reaction of the tissues as evidenced by epithelitis of the mucosa or epidermitis of the skin is present.

The only excuses for having the temerity to demonstrate such applicators must be the usual poor results generally reported to date in this country in the treatment of such types of lesious, especially in the esophagus under radiation treatment in contra-distinction to the more optimistic reports from abroad. It is hoped that these applicators may benefit these patients

CARDIOSPASM AND OTHER OBSTRUCTIONS OF THE UPPER GASTRO-INTES-TINAL TRACT IN THE NEW BORN

By JOHN AIKMAN, M.D., ROCHESTER, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, on April 5, 1933

VOMITING in infants has always been an annoying problem to the physician and it is only in recent years that we have learned more of the causes and how to treat them. It is my plan to consider vomiting as it occurs in the newly born and in very young memory.

fants. In the majority of these cases an early diagnosis leads to successful treatment, while needless delay and leaving improvement to nature may cause disastrons results.

The small infant stands continuous vomituig poorly and soon shows loss of weight and marked signs of dehydration. Every effort should promptly be made to determine the cause of vomiting in these cases while the infants are still good operative risks.

The causes that are most often found in these small infants are shown on the following chart. We shall consider some of the more

important of these.

Causes of Vomiting in the New Born

Overfilled stomach
Aerophagy, air swallowing (Gas)
Indigestion, improper feeding
Low tone of Cardia
Hunger—Too fretful
Toxemia of mother or infant
Cerebral hemorrhage
Reflex from pharynx
(From over large or long nipples)
(From fingers in mouth)
Congenital Pyloric Stenosis Pylorospasm

Congenital Tyloric Stenosis Tylorospass Congenital Stenosis of the Esophagus Congenital Intestinal Obstruction Swallowed anniotic fluid Acute infections

Acute infections
Hemorrhagic disease
Congenital Syphilis
Peritonitis
Obstructed hernia

(Especially diaphragmatic)

Fortunately most of the vomiting of the new born is of little consequence, frequently being no more than simple regurgitation. As vonReuss las stated the cardiac orifice of some children may show little tone, permitting the easy return of food from the stomach to the esophagus. Regurgitation is also aided by the fact that the cardia is not valve like as is the pylorus. This easy return from no particular cause can be seen when these children are fed under the fluoroscope, the amount lost in this way is usually of little importance. Such children should be handled as little as possible as the handling increases vomiting.

Over-filling of the stomach when the food supply is abundant is a very common cause of mild vomiting. The overflow need give no worry, if the child is making normal gains in weight. Over-filling will be cared for because as time goes on the breast supply is apt to become reduced and the stomach also to in-

crease in capacity.

The English attach great importance to air swallowing as an etiological factor. Certainly infants do swallow air, especially if the child's mouth does not fit well about the nipple or if there is interference with nasal breathing. This latter may be due to any retro pharyngeal, pharyngeal, or nasal obstructions. It also oc-

curs in nervous, restless, hypertonic infants. The child swallows as much air as he does milk, the stomach becomes distended and with the eructation of the air a large portion of the milk is expelled. Children that are too hungry may vomit from this cause.

If the nose is obstructed a drop of adrenalin in each nostril makes nursing easier. If bottle fed, the nipple may be changed, a larger nipple sometimes helps. Holding the child up-right against the nurse's shoulder several times during nursing will help to expel the air with less loss of milk.

The fact that the English treat this condition successfully with both atropine and with thick cereal feedings leads one to the conclusion that many of the cases classified under air swallowing are the type that we call pylorospasm. Gas or air as a cause of vomiting does not hold as prominent a place in the American school.

Indigestion due to improper feeding may occur in maternity nurseries, but not as frequently as formerly. The usual cause was too high fat in the formula. The widespread use of milk from Holstein cows has lessened this danger. Too high sugar may cause vomiting, but not usually.

Cases in which the mother's milk is said not to agree with the child are more apt to be due to other causes that we have under discussion. We have rarely found human milk to be the cause of vomiting. The use of certain synthetic substitutes for human milk may, however, occasionally upset the child.

It seems to us that the best formulas in nurseries are the simple dilutions of milk with a reasonable addition of Karo corn syrup or of

some sugar like Dextri Maltose.

Of course all the cows' milk given to these infants should be boiled. The makers of every substitute for mother's milk are constantly on the alert and are working to have their various foods introduced into maternity nurseries. The business reason is obvious. Many of these foods are of value but they are rarely necessary. The value of lactic acid milk, freshly prepared daily, should not be overlooked because many American pediatricians hold that it is the best artificial feeding.

Some children will vomit more on the four hour than on the three hour schedule because of the required larger amount at each feeding.

Vomiting may occur as a result of acute infections, peritonitis and any septic conditions. Frequent vomiting may accompany cerebral haemorrhage of the new born or hemorrhagic disease of the new born. Coughs due to upper respitatory or lung infections may produce vomiting and we must not forget the pharyngeal reflex due to the child placing his fingers too far

back in the month. Vointing of the newly born may be due to large amounts of anontotic fluid

that have been swallowed

The other causes of vomiting on the outline are of a congenital nature While some of them are given but little attention in text books of pediatrics I hope to show that these causes are not as rare as we might think and that they present fairly distinct and definite symptoms, permitting accurate diagnosis

Fortunately most of these conditions yield to proper treatment if recognition is not too much delayed Early diagnosis and prompt treatment are the keys to success. As said before, constant vomiting soon causes serious fluid loss making the prognosis less favorable as

hours and days pass without relief

One is always impressed with the wide range of malformations that may occur in the liu-Almost any departure from the man body normal that we can imagine may be found This is true in the gastro intestinal tract However, certain deformities occur far more frequently than others and each has a tendency to give a fairly clear pathological and clinical pieture

The following cases illustrate the pathologic cal and clinical pictures presented by some of the rarer cases of comiting that we have

studied

ATRESIA OF THE ESOPHAGUS

The most common gross deformity of the esophagus is the one here presented. The upper portion of the esophagus ends in a blind pouch or cul de sac at about the level of the bifurcation of the trachea. The lower portion of the esophagus extends from the stomach to the trachea A cord like central portion with no opening may connect the two parts of the esophagus Many of these cases have been reported in the literature and four have been described in the last few months in this coun Any departures from this anatomical picture may occur but most of them present much the same features

It is usually found in children who are otherwise well developed Nothing abnormal is noticed until the child is first fed Then the baby acts as if it had "swallowed the wrong way' and as the fluid in cul-de sac gets into the trachea severe choking, strangling and vomiting occur Much air is mixed with the mucus as it bubbles, frothlike, from the mouth and This occurs whenever food is taken The food regurgitated is unchanged and alkaline Cleft palate will sometimes give a similar picture but can easily be ruled out. The stom ach becomes very much distended. As soon as the meconium is evacuated complete constipation occurs

A catheter passed into the esophagus will show at what level the obstruction has occur red. Cases are reported in which an attempt has been made to feed these children through Food and barium then pass a gastrostomy into the trachea produce pneumonia and hasten the child's death. This inistake can be avoided by a careful a-ray study of the esophagus using lipiodol or similar preparations in the place of barrum. If the x ray shows a clear chest no communication with the traclica may be pres It has been suggested that hipsodol be placed in the stomach through the gastrostomy to see if such a communication is present and then possibly shutting off this lower portion of the esophagus in some way by surgery have found no record of a favorable outcom but surgeons feel that partial cure may be pos Foreign matter getting into the lung from either the cul de sac or the stomach pro duces pulmonary involvement or the child

gradually dies of starvation J M, male child, born August 9, 1928, full term, labor spontaneous Tamily history neg ative, one other child living and well Adm t ted to the Strong Memorial Hospital on the 5th day because of mability to take food Was cyanotie at birth, given oxygen several times was choked with mucus Became choked and cyanotic when nursed Regurgitated following

feeding

A tube passed into the esophagus met com plete obstruction Barium apparently did not go below the upper third

Physical examination, weight 3350 gms somewhat delightated, milk present in the nose and mouth, breathing noisy Breath sounds loud and harsh Otherwise negative

A gastrostomy was performed by Dr Merle Scott on August 15, 1928 Food fed through the gastrostomy was regurgitated through the mouth Two days later a transec tion of the stomach was done. The patient had a gradual but steady loss of weight oped broucho pneumonia September 8, 1928, and died on September 12, 1928

At autopsy it was found that the upper portion of the esophagus ended in a blind pouch while the lower portion connected the stomach and trachea

STENOSIS OF THE ESOPHAGUS

Stenosis of the esophagus is less common than the atressa mentioned and produces vom-iting from an early date. This becomes worse as the child is given semisolid and solid food The following case illustrates the symptoms as well as the diagnosis and treatment

I G, girl seen first by me on November 21, 1927, when 8 years of age Began to vomit breast milk at 2 months of age and has vomited a por

tion of her food ever since. Vomiting not projectile. Weaned and put on all sorts of food without improvement. Bottle fed until 3 years of age and had never taken solid food well. Milk when vomited came up sweet, not curdled. No nausea. Hungry and wanted immediate refeeding. Constipated. Had been seen by ten different doctors during her life and at 3 years of age had an x-ray examination. The bowel was then said to have been enlarged but no obstruction was found. The patient was admitted to the Strong Memorial Hospital.

She was a thin, tall, starved looking girl. Showed scoliosis. The chest gave evidence of old rickets. Teeth showed decay. Fluoroscopic examination showed that food stopped at the hilus region and that a conical pouch developed. During ten minutes observation no food entered the stomach. No reverse peristalsis was noted. Atropine administration followed x-ray, examination showed the spasm played some part in the obstruction. Direct esophagoscopy by Dr. Heatley gave no evidence of scarring. Diagnosis congenital stricture.

The stricture was gradually dilated by bougies In 2 weeks barium passed readily but the point of obstruction could still be identified. Child could eat with the family and did not act starved

all the time.

After all her years of illness this child was a great management problem. Her vomiting attacks have shown recurrence both for psychological and obstructive reasons. She has been readmitted a number of times for dilation of the stricture. While she gained in weight and has been very much better in health she is still below normal for her age.

Earlier recognition of the stricture with prompt treatment would have saved years of suffering and would also have given better results. Had fluoroscopic examination been made early in infancy much better results would have been obtained. It is interesting that no diverticulum has

occurred

CARDIOSPASM

It has been known for many years that spasmlike obstruction may occur at the cardiac end of This is generally attributed to a the stomach. spasm of the smooth muscle fibers surrounding the cardiac orifice. Some writers, believing that there is no regular sphincter at this point, claim that the crura of the diaphragm act as sphincter and call the condition phrenospasm. The condition is probably due to a disturbance of the vagus control of the cardia. Masseloff in 1928 stated that in over 20,000 roentgen ray studies made at Bellevue Hospital during 6 years only one case of cardiospasm had occurred in a child as young as 11\years of age. He found only 11 authentic cases reported in infancy and childhood. Moersch in 1929 reviewed 691 consecutive cases of cardiospasm seen at the Mayo Clinic. Only 12 of these were diagnosed before 14 years of age. In but three had the symptoms been noted during the first year of life and the diagnosis was not made until adult life.

Birnberg in 1929 could not find that the diagnosis had been recorded in a new-born infant. At that time he reported three cases in new-born infants, two recovered but the third died on the fourth day of cerebral hemorrhage.

He suggests that cardiospasm exists more commonly than has been suspected and that it should be considered as a possibility in vomiting of early

infancy.

R. B. (Fig. 1), male, born November 12, 1930, at the Genesee Hospital, birth weight 7½ pounds. He began to regurgitate on the first day. Most of the vomitus was sweet but some curds were noted. He vomited immediately after nursing and cried a great deal. He had lost one pound and four ounces when I first saw him on his fourth day. There was no visible peristalsis and no tumor. Pyloric stenosis or cardiospasm were

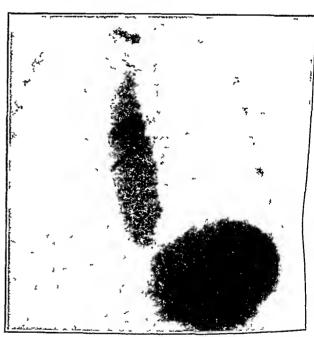

Fig 1 Cardiospasm, Boy, R. B, 6 days of age.

suspected and he was given atropine. He did a little better. Two days later x-ray and fluoroscopic examinations showed that barium hesitated before entering the stomach and that the esophagus became markedly dilated. Three hours later barium was still present in the esophagus and also in the stomach and intestine.

A diagnosis of cardiospasm was made and under the fluoroscope a number 8 catheter filled with the barium mixture was easily passed into the stomach. The catheter was left in for 2

d results by such

treatment. The baby was given atropine until flushing occurred but the catheter feedings had to be given on several occasions for 24 hours. By December 27th the weight was 8½ pounds and he had been put on concentrated feedings of dry lactic acid milk He was fed through the tube if the vomiting was severe.

X-ray and fluoroscopic examinations all showed definite delay in the passage of food into the stomach also dilatation of the esophagus. He was

discharged from the hospital.

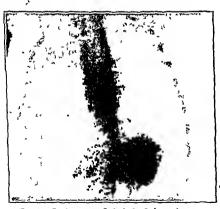

He was readmitted January 26, 1931, and gained up to 10½ pounds. Atropine was given and the catheter was passed without the fluoroscope as a guide. In June he was readmitted and the catheter passed X-ray studies showed little change

At this time Dr. George Carroll passed a dilator threaded on silk thread. At one time through misunderstanding, thread was fed to the baby until one end passed through the rectum

He was redilated in September.

The child gained in weight and would go for long periods without vomiting. To all appearances he was a perfectly normal child. He had pneumonia in February, 1932, and was admitted to the Strong Memorial Hospital. The esophagus gave the same x-ray evidence. He made a good recovery from the lung infection When last heard from a few months ago he was gaining in weight.

J L (Fig 2), female, born at Genesee Hospital December 19, 1932 Birth weight 7½ pounds

Tig 2 Cardiospasm, Girl, J L, 5 days of age.

First child in family, mother had had bronchiecstasis for years Baby began to vomit on second day. Regurgitated some at each feeding Sometimes vomiting was projectile.

First examination by me on December 20th.

Child seemed normal in every way, no pathology. A diet of skimmed milk was given and atronne 1/1000 grain was administered before each feed-The vomiting coning X-ray study ordered tinued. There was some delay in following out orders and on December 24, the fifth day of life, a fluoroscopic examination revealed marked delay at the esophageal opening of the stomach obstruction was not complete as some of the barium did pass through. On the same day under fluoroscope a small catheter filled with barium was passed into the stomach and barium was seen in the intestine 1/2 hour later. A diagnosis of cardiospasm was made. The catheter was left in but had to be replaced several times. Food There was no was given through this tube. vomiting after tube feedings and the tube was left in as much as possible for 4 days. After that it was passed frequently and was discontinued on January 1st. The child had practically no vomiting.

On January 4th the fluoroscope showed no appreciable hesitancy of food at the cardia. Weight

7 pounds 12 ounces

The child was sent home on a formula of boiled milk, Karo syrup and water. She gained steadily, had no more vomiting and at 7½ months weighed 21 pounds 6 ounces

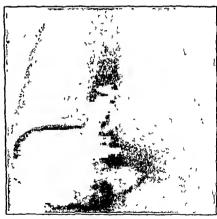

Fig 3 Cardiospasm, Boy, B. J. 3 days of age.

B J (Fig. 3), male, born at the Genesee Hospital on January 24th, birth weight 7½ pounds. Vomited from the first feeding. Vomitus sweet, no curds Examined by me on the second day. Nothing pathological detected. Diagnosis, possible pylorospasm. Given fat free milk and atropine.

X-ray and fluoroscopic examination on the third day showed marked delay at the cardia and

the esophagus was dilated. Three hours later barium was still present in the esophagus but was also seen in the stomach and intestines. Diagnosis, cardiospasm.

A catheter was passed and the child was fed breast milk through this for 18 hours. After that the catheter was passed occasionally and atropine was given. There was no more vomiting and on the 14th day the child left the hospital.

The family left Rochester and the child was put under the care of Dr. H. L. Bibby of Kingston, N. Y. The doctor reports that the baby had no more vomiting. "It gained steadily and was in excellent nutrition."

The baby died suddenly on October 25th, 1932 and "it was considered a thymic death" reports Dr. Bibby, "in spite of all our troubled and uncertain knowledge of that condition." The thymus was about two and one-half times the normal size, most of the increase being in the anteroposterior diameter. There was no pathology at the cardia but the esophagus showed a slight dilutation.

There were no signs of thymic enlargement during life but the parents thought that the baby was somewhat pale and that the face became flushed during feedings for one week before death.

While the shadow of the upper mediastinum is somewhat broad several roentgenologists have stated that a lateral view would have been necessary for a diagnosis of thymic enlargement.

M. S., female, born May 26, 1932 at Strong Memorial Hospital, family history, first child, mother normal, father unknown. Nothing abnormal detected. Sent home and returned at regular intervals to the Out Patient Department.

Was admitted October 25, 1932 at 5 months of age because of repeated vomiting at various intervals between meals and because of malnutri-Was said to have always vomited an abnormal amount. Even vomited when asleep Weight 11 pounds. Was kept in hospital and did fairly well, gained a little from time to time. On December 2nd because of more severe vomiting a fluoroscopic examination was made. There was definite delay at the cardiac end of the esophagus with moderate dilitation above this point. A fair sized residue in the esophagus showed a to and fro motion. The same was noted when the child was held in an erect posture. There was no regurgitation of barium from the stomach. child retained thick cereal fairly well

Baby B, (Fig. 4) female, born September 25, 1932 at the Genesee Hospital, first child, family history negative, birth weight 8 pounds.

Began to regurgitate on the second day and by September 30th had lost one pound. Vomited directly after each feeding, varied from regurgitation to projectile vomiting.

Physical examination—no pathology was de-

tected. The abdomen gave no evidence of visible peristalsis or tumor.

The child was given atropine and fat free On October 1st x-ray examination gave evidence of cardiospasm also dilatation of the esophagus and there was marked delay in the passage of food through the pylorus. The child was given intra peritonial saline. A catheter was easily passed through the nose into the stomach Breast milk was injected. A short time later both the milk and catheter were vomited. This was repeated several times and attempts were made to give cereal through a larger catheter. Projectile vomiting continued and on October 3rd a Rammstedt operation was performed by Dr. Douglas Mitchell. The pylorus was found to be markedly thickened.

The child had a very stormy convalescence. Saline was repeatedly given by hypodermoclysis. Atropine was administered and thick cereal was given. After a week the child began to improve and gained in weight. Discharged October 22nd.

Fig. 4. Cardiospasm and Pyloric Stenosis, Girl, Baby B , 7 days of age.

Since then the child has had little or no vomiting and has continued on thick cereal feeding. It seems to be normal in every way.

Pyloric stenosis was the primary cause of vomiting, the cardiospasm being of but little importance.

Conclusions

New-born children with cardiospasm vomit during or just after feedings, the vomitus contains little or no gastric juice. Vomiting dates from the first attempts at feeding. It is accompanied by the usual results of vomiting loss of weight, dehydration and constipation The eon dition is easily found by fluoroscopic examina-

A small sized eatheter passed through the nose into the stomach may be left in place for one or two days and later replaced at intervals child is fed through this tube. This gives good results iii most cases

Cardiospasm is not well understood but it is probably only a temporary affair in most cases Many such eases may have eleared up in the past under atropine and thick feeding without the condition of the cardin being known. They have probably been considered pylorospasm On the other hand any continued vomiting is dangerous in the new born It is also possible that a continuation of the eardiospasm may lead to dilatation of the esophagus

Many pediatricians are interested in this subtect and more cases of cardiospasm have been found in the last three years than literature indicates

It seems that we have here a condition that is being overlooked but which would be more frequently found if the esophagus and stomach of all infants with continued vomiting were subject ed to fluoroscopic and 1 ray examinations Such examinations will certainly lead to more accurate unagnosis of the condition present

Pylorospasm and Pyloric Stenosis

So much has been written about these conditions that very little need be said here. Pyloro spasm is generally considered in this eoi ntry as a mild or moderate form of Pyloric Stenosis

In these children the symptoms yield fairly well to the use of atropine just before feedings and to thick feedings It is probably much the same condition as is frequently diagnosed in England as air swallowing, accounting for the fewer cases of pyloric stenosis discovered in that country

Congenital hypertrophic stenosis of the pylorus occurs usually in male infants after the first week or two of life, but as we have seen it may be

present earlier

Habitual, forcible, projectile vomiting is charaeteristic of this condition. It may come during the feeding when the fool is but little changed or a portion of the food may remain in the stomach until the next feeding when it is then vomited The bowels are constipated and the urine scanty Wasting and dehydration progress rapidly

The two characteristic symptoms, visible re verse peristalsis and palpable tumor are not al They are more apt to be found in ways present the case that has been allowed to go for a long time before operation. The marked loss of weight in these eases makes the physical signs more evident

The prolonged retention is demonstrated when

the child vomits several hours after feeding a stomach tube may be passed 2 or 3 hours after feeding to determine gastric retention. Up until recently the a ray was not considered necessary for diagnosis. We believe however that it is of considerable value because some of the conditions we have mentioned may also be present

When children have continued projectile vomiting during the first six weeks of life in spite of atropine, thick feeding and most eareful nursing, one must always lean strongly to the diag-

nosis of pylorie stenosis

When pyloric stenosis is suspected the patient must be kept under elose supervision either at home or in the hospital The amount of vomiting must be recorded and the child weighed daily Continued voiniting with loss of weight make operative interference more imperative

The operation in experienced hands gives excellent results but we find that many of the pa tients regurgitate for a few hours or days after

the operation

DUODINAL OBSTRUCTION

All sorts of congenital intestinal obstruction may occur and at any point. We will consider only obstruction of the duodenum cause it is the most common site for eongenital intestinal obstruction second, because it may be confused with pyloric stenosis and also because surgical intervention frequently gives good results

Of 200 cases of congenital intestinal obstruetion, vonReuss found that 1/3 were in the duodenum, usually an atresia. In the jejunum and ileum obstructions are more likely to be multiple and the intestine to be merely a band like strue

When vomitus in congenital obstruction is bile stained we must suspect the duodenum, but if the obstruction is above the papilla there may be no bile in the vomitus According to Cameron in more than 80%, the vonitus is brightly stained The vomiting begins from the first to with bile the third day occurring soon after feedings is profuse but not projectile

Faint peristalic waves may be seen but there is usually no tumor There is seldom a general dis tension of the abdomen The obstruction is usu ally due to a diaphragm in the limen of the bowel but it may be due to abnormalities of in testinal rotation, volvulus kinking, obstruction by peritoneal bands or obstruction by the superior mesenteric artery as it passes into the root of the mesentery

X ray and fluoroscopic examination lead to the diagnosis and rule out the obstructions above the duodenum especially pylorie stenosis

We are able through the courtesy of Dr Morton of the Strong Memorial to report two eases M L, a female child born at the Strong Me

morial Hospital on May 22, 1932. Family history negative. Three other children living and well. Born full term and normal delivery. Birth weight 3350 grams. Given formula of milk, karo and water.

Began to vomit on the 5th day. Physical exam. was negative until the 11th day, when left otitis

media developed, incised.

On the 12th day the vomiting became projectile and peristolic waves were seen, x-ray examination showed definite obstruction apparently in duodenum. Weight 2610 grams. Was given a transfusion and also saline by hypodermoclysis before operation. Dr. John Morton at operation found an obstruction of the duodenum. Gas could not pass this point. On incision of the bowel a diaphragm 2 m.m. in thickness and apparently blocking the lumen was found. The diaphragm was burned down and the intestinal lumen restored.

The vomiting continued on and off following operation. An x-ray examination after the operation showed some delay in emptying time, but barium passed freely through the upper part of

the small intestine.

The child who had dropped to 2600 G. gained until the weight was 3440 G. on July 13, 1932

when he was discharged.

On September 28, 1932 the stomach was found enlarged for the age. The dilated portion of the duodenum was still present. There was some delay in emptying time.

B. S., female, born at the Strong Memorial Hospital on May 1, 1930. Birth weight 2600 grams, family history negative, fourth child.

On the third day it was reported that she passed no meconium or urine for 24 hours and had sev-

eral times vomited a thin brownish fluid.

The abdomen was thin walled and soft. A tubular mass like distended gut was palpated below the left costal margin to the right flank. Some reverse peristalsis was seen. Was given a barium enema and it was thought that a colonic obstruction was present.

On the fourth day she passed meconium but no fecal material. Vomiting was marked and the tumor was still present. On the fifth day she was operated upon by Dr. T. B. Jones and an obstruction was found at the third portion of the

duodenum due to either a diaphragm in the lumen or to a lack of the third portion of the duodenum. It was obstructed at the point where the superior mesenteric artery crosses over the duodenum. A posterior gastroenterostomy was performed.

The child had a normal stool on the second day

after operation and made good recovery.

On May 17th an x-ray examination showed good function from the gastroenterostomy.

The child was readmitted on January 4, 1932 with Mongolian Idiocy and pneumonia. Died.

The results in these two cases demonstrate that obstruction of the duodenum may be diagnosed

and treated successfully.

When congenital intestinal obstruction is suspected x-ray studies may lead to the correct diagnosis. The excellent results reported in these two cases offer us a better prognosis as most congenital obstructions occur at this point.

Malformations beyond the duodenum will not be considered but they are not hopeless as some

have recovered after operation.

By this review of vomiting in the newly born I hope that we have shown that a definite diagnosis as to the cause can frequently be made. Better diagnosis leads to improvement in treatment.

Every new-born child with persistent and unexplained vomiting should be given a complete roentgenological and fluoroscopic examination. Early diagnosis and removal of any cause of vomiting may prevent delaydration, loss of weight, and even death.

Conclusions
